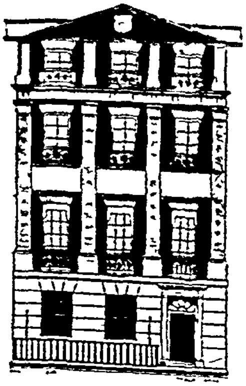
THE LANCET

JOURNAL OF BRITISH AND FOREIGN MEDICINE, SURGERY, OBSTETRICS,
HYSIOLOGY, CHEMISTRY, PHARMACOLOGY, PUBLIC HEALTH, AND NEWS

FOUNDED BY THOMAS WAKLEY IN 1823

VOLUME TWO
JULY-DECEMBER
1942
VOL. No. CCXLIII

EDITED BY
EGBERT MORLAND, M.D., F.R.C.P. & S.
WITH THE ASSISTANCE OF
T. F. FOX, M.D., AND E. CLAYTON-JONES, M.B.



PUBLISHED BY
THE LANCET LIMITED
ADAM STREET, ADELPHI, LONDON, W.C.2

INDEX TO VOLUME II, 1942

REFERENCES AND ABBREVIATIONS

iders in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings. Institutions and Corporations with the right to the prefix Royal will be found under that prefix, with the exception of Hospitals which will be found under that heading, and Medical Societies, which are separately indexed under Societies. All Universities are indexed under the word University. (A) = Annotation, (C) = Correspondence, (LA) = Leading Article, (ML) = Medico legal, (NI) = New Invention, (O) = Obituary, (P) = Parliament and (R) = Review

A Concordance of page numbers and dates of issue will be found on page xix

CHRONIC HEAD CASES

CHARLES ANDERSON, M B LOND, M R C P
NEUROPSYCHIATRIST TO THE EMS

MAN's old belief that damage to the vital centres profoundly upsets the balance of the personality finds some support from careful psychiatric observation, man's common belief that *any* blow to these centres must produce far-reaching changes is not substantiated, but the notion dies hard. Patients commonly entertain the notion that the head is a fragile box filled with precious objects, such as thoughts, and vaguely defined vital centres After an injury the resulting change in the personality and capacity for work is attributed to damage to the contents of the box, and the complaint of headache is in many cases a response to the patient's discontent with his own emotional and intellectual capacities, though defects of these may have been present before the injury Now he can explain why he has failed: "I have a headache."

PRESENT INVESTIGATION

A group of 150 consecutive admissions of Service patients to a neurosis centre, in whom head injury was held responsible for the symptoms, were investigated Taken as a group their symptomatology did not suggest a simple syndrome; but if grouped according to the usual personality reactions used in psychiatry their response to a knock on the head could be seen in relation to their behaviour-reactions to other and non-traumatic experiences. In some, physical trauma actually played no part, but they could more easily contemplate an external or physical experience than face the disturbing fact that they were not masters of their own thoughts and moods; they said their heads were damaged, but what disturbed them was the sudden realisation that their self-confidence when confronted with emotion (not danger) had gone In other cases the external event acted as a precipitating factor in the production of neurotic or psychotic reactions, in still others the symptoms were due purely to organic damage; and in a last group there were organic residua to which were added neurotic or psychotic symptoms

The duration of symptoms before admission ranged from 2 years to 7 weeks, with an average of 10 months, most of the patients had already sojourned in three or four hospitals, 11 had been in five hospitals and many—owing to long but interrupted hospital care and medical mismanagement—had become useless in the performance of even the simplest fatigues Their first stay in hospital had usually lasted a month, and most of them had spent about 3 weeks in bed after their accident, though 23 had been kept in bed only a week; of these 15 were sent back to duty with daily headaches

The length of retrograde and post-traumatic amnesia bore no relation to the severity of the subsequent symptoms; indeed 12 patients who were only temporarily dazed developed severe and protracted sequelæ, organic in origin, and it was this group particularly who were kept in bed for too short a period and labelled neurotics or malingerers Those who sustained longer periods of unconsciousness received far more thorough support treatment When judging the degree of pre- and post-traumatic amnesia it is important to realise that these normally diminish with the passage of time, till a stable minimum of events is forgotten. The boundary of a post-traumatic amnesia is not absolute or permanent, there are islets of memory which gradually increase in size and coalesce till only a small part of the scene is in permanent scotoma Retrograde amnesia is both more permanent and more sharply defined though it too gradually diminishes In the following case-histories the periods of amnesia are those last given me by the patients, not those put in the first records of their illness nor those they mentioned first on admission

The complaints varied from single symptoms to a wide span of disabilities, the latter being characteristic of neurotic reactions, though in a proportion of these, particularly the obsessional, attention was focused on a single disability Symptoms and their distribution was as shown in the following table.

Headache, the most constant complaint, was absent in only a small proportion of cases, all of whom showed organic sequelæ, and it was impossible to differentiate between neurotic and organic headaches by an investigation of the clinical variations of this single symptom, which was made worse in all types by shaking or changes in posture

Symptoms

Headaches	138	Fugues and non traumatic amnesias	7
Giddiness	129	Change in character, apart from irritability	4
Faints and blackouts	52	Deterioration of visual capacity—	
Much irritability	39	organic	1
Minor affective disorders (mild depressions)	83	hysterical	5
Major affective disorders (manic-depressive response)	13	Squints	7
Impaired concentration and memory	116	Deafness	2
Hysterical fits	9	Cortical paresis, anæsthesias, agnosias and apraxias	3
Epileptic fits	2	Impotence	8

True intellectual deterioration and epileptic fits are signs of structural damage, but superficially similar symptoms such as impaired concentration and blackouts occurred in both neurotic and traumatic reactions Neurological signs were of course pointers towards organic damage but were seen in only 7% of cases

No one sign or symptom or one group of signs or symptoms, is pathognomonic of psychogenic or physiogenic reactions, the duration of disabilities is no guide to their origin and it is only by assessing the personality as a whole and its reactions to psychical or physical traumata, that a true evaluation of the origin and nature of symptoms can be reached

Physical, neurological, psychometric and psychiatric investigations, and examination of the cerebrospinal fluid were routine, air encephalography was done in the few cases showing intellectual deterioration with raised protein in the CSF suggestive of internal hydrocephalus due to cerebral atrophy or arteriopathy.

Psychometric examination helps to differentiate reaction types, gives an objective measure of the degree of deterioration and is thus useful in prognosis The tests used were Penrose and Raven's progressive matrices, Terman (Stanford revision) battery and vocabulary tests, form boards, Kohs designs, Passalon test and the Babcock deterioration test

Response to head injury (as to any other trauma or disease) depends on the patient's general habit of response to change as well as to the organic change produced by the injury, his general mode of response is itself determined by constitutional factors and by factors which influence him (particularly in his earliest years) during his development The object of classification should be to systematise the different reaction types

I could parallel the findings given in this paper from a series of reactions following cerebrospinal meningitis. Indeed, had I been presented with the clinical findings without details of the accident and amnesias in most instances I would have been hard put to it to judge whether a case was one of injury or infection

NEUROTIC REACTIONS

The largest group was made up of psychoneurotic reactions and contained 69 patients, of whom 62 were hysterics and 7 obsessionals Most of these had had previous neurotic disturbances and were unstable personalities, many were unable or appeared unwilling to adjust themselves to harder environmental conditions They had a considerable amount of latent and misdirected aggressiveness and showed an obvious desire to regain the securities of family life away from the discomfort and insecurity of military service Yet there were a fair number of apparently well-integrated and stable personalities who had reacted well to Army life up to the time of their injury; this seemed to have acted as a trigger in releasing neurotic reactions, due largely to guilt over feelings of fear and to incapacity to deal with the hate which active warfare aroused. In addition there were 5 mental defectives whose responses to trauma arose from anxiety about their inability to fit in with a skilled, mobile and mechanised Army. The ruminative, tense obsessional cases were of a different kidney, focusing their doubt, indecision and compulsive preoccupations on their injured head; at the same time they begged to be allowed to return to their duties, though knowing that they would be unable to perform them satisfactorily. When faced with these compulsive demands for distraction from brooding it was essential to discriminate between the element of keenness for work and an almost hypomanic denial of emotional problems

CASE 1 —A gunner of 23 was sent in as a possible traumatic epileptic He had daily headaches and numerous bouts of falling to the ground He was pushed off a bridge during the retreat to Dunkirk, struck his head and was unconscious for about 3 hours with a few seconds retrograde amnesia He managed to make his way to the beaches in a dazed condition and was eventually picked up After return to England he was put on police duties and then at his own request was transferred back to a gun team The headaches, which had been present since the injury, increased in intensity, and he developed numerous attacks of falling to the ground in a state of apparent unconsciousness both on duty and at his billet, he often struck his head during these bouts and once fell downstairs He was a large healthy boy who had worked in civil life as a steel riveter, where he was stable, active, sociable and without any fears He stolidly denied any feelings of fear during his period of active fighting and was disgruntled and aggressive He abreacted violently under narco analysis "I couldn't stick the guns, I'm scared, I shouldn't be yellow, I'm too big for that, all the chaps thought I was tough" Subsequently, with further explanation, he became symptom free but had to be discharged from the Army in view of his instability and liability to relapse

His symptoms were hysterical reactions to his feelings of fear and rage, and he was typical of many who erected façades of aggressiveness in order to deny their inner insecurities

CASE 2 —A gunner of 26 was admitted with headaches, palpitations, insomnia, giddiness and depression dating from a head injury 10 months before when he was unconscious for 6 hours and had about 5 minutes retrograde amnesia His twin sister died shortly after birth; he always felt his parents would rather have had a daughter than him, wished he was a girl and was nervous and out of place all his life He was unhappy at school, later held numerous jobs of a few weeks' duration and was often off work with headaches His chief interest in life was music and he played the village organ He reacted poorly to enlistment, was miserable and solitary for a long time, often wept and could think of nothing but his mother and the coarse behaviour of his comrades He gradually became acclimatised to his altered environment, organised a jazz band and felt better till his head injury occurred

In contrast to the first case, this patient had always been unstable and neurotic, largely owing to latent homosexuality of which he was himself unaware, and his response to trauma consisted of increased anxiety feelings towards this condition of homosexuality

CASE 3 —A private of 24 complained of headaches, trembling, palpitations and depression, dating from a slight scalp wound 9 months before, when he fell from a haystack on to wet grass and was dazed for a few seconds He was terrified of a strict father and had had attacks of headache as far back as he could remember He left school at 14 in standard 4 (top standard 7), had about twelve jobs subsequently with 3 years total unemployment and was a tea masher before enlistment[1] He reacted fairly well at first to Army life as he had joined up at the same time as an older friend who promised his wife and mother that he would look after him He was slow and awkward at drill and often reprimanded, he soon got separated from his substitute father, became miserable, had numerous headaches and finally after his slight head injury was a constant attendant at sick parades His performance with progressive matricies was 23 in 50 minutes (the score of a person of average intelligence not disturbed by anxiety or affective disturbances would be between 40 and 50 in this time) He was a defective lad who had used his slight injury as a peg on which to hang his inability to adjust himself to the stress of Army life

CASE 4 —A corporal of 27 was concussed 13 months before admission, unconscious for 30 minutes, had about 2 minutes retrograde amnesia and was in hospital 5 weeks Since then he had had headaches, dizziness and blackouts, could not concentrate and slept poorly He had always been conscientious, punctilious and a worrier, he had a predilection for figures particularly number 3 He was keen to get on in the Army, worked hard and efficiently, would be thinking constantly of his duties even during his free hours and was in fear of making mistakes and losing his stripes After accident, on return to duty he was anxious about his effici at work, worried about the attitude of his wife and o if he failed, and was in a permanent state of indecision a his activities, beliefs and ideals He was in hospital three times and on one occasion wandered off in a fugue lasting [illegible] days He felt that damage from his concussion was responsible for his symptoms, feared his mental capacity had been permanently altered and often referred to his terrible headaches and his poor head, which became the centre point of all his thoughts

This patient illustrates the reactions of an obsessional personality who became tense and ruminative after a slight head injury which released and accentuated his conflicting feelings.

ORGANIC SEQUELÆ

A group of 56 patients presented symptoms which were held to be physiogenic in origin All had retrograde amnesia, 12 were dazed for a few minutes and the rest had varying periods of confusion up to 10 days In 23 intellectual deterioration could be demonstrated psychometrically, and of these 6 had no headaches and 4 were almost certainly mental defectives—judged by school and work records—whose limited capacities were still further curtailed by injuries to which such people are often exposed through lack of reasonable foresight In 26 the only complaint was of headaches, varying in intensity, made worse and accompanied by dizziness or blackouts on exertion There were 4 who showed definite changes in character, 2 of these were epileptics, of whom one had been concussed in civil life and had been attending hospital for some years before enlisting, 2 were punch-drunk boxers of whom one was involved in a lorry accident. Only 10 cases presented neurological signs such as ocular palsies, nerve deafness or astereognosis Previous severe head injuries involving hospitalisation, changes in memory and absence from school or work were reported in 3 patients and these had severe and protracted symptoms

CASE 5 —A gunner of 24 complained of headaches and impaired concentration and memory. A stable, active lad, he had matriculated and worked as a traveller until enlistment, when he was put on radiolocation and hoped for a commission He had been concussed 12 months before and had about an hour's retrograde and 8 days post traumatic amnesia He was kept in hospital 6 weeks and after 3 weeks sick leave returned to duty in the Orkneys where he had daily headaches, felt giddy, saw double and could not carry on with radiolocation as his eyes and head throbbed He tried to resume reading but could remember nothing of what he read, his writing deteriorated and he had difficulty in spelling He ran a canteen but felt he was a nuisance and a burden and that his injury kept him from the success he so much desired His performance with progressive matricies was 31 in 75 minutes, though his level of intelligence was such that prior to his injury he should have scored about 56, the Terman battery and vocabulary tests gave mental ages of 12½ and 15 years respectively (a characteristic discrepancy in traumatic cases), and his performance with form boards was better than that with Koh's cubes and the Passalon test After 3 months treatment his matricies increased to 45 in 50 minutes, his responses to the Terman battery and vocabulary tests gave mental ages of 14 and 16 years respectively and his performance with Koh's cubes and the Passalon test was much improved

This lad developed intellectual deterioration and though resenting his disability eventually accepted it without developing neurotic reactions

CASE 6 —A driver of 22 was concussed 16 months ago and had a retrograde amnesia of 30 minutes and a post-traumatic amnesia of 8 days Before this he gave no history of nervous disorder and was an active, cheerful, happy go lucky type He was in hospital 4 weeks and after 3 weeks sick leave returned to duty where he was depressed and disgruntled at everything, had difficulty in concentrating, showed lack of initiative, would start work but could not keep to any plan, became asocial, avoided his parents and fiancée and spent a further 3 months in hospital without much improvement On examination he was tense, irritable, depressed, restless, anxious to stand during interviews, and appeared to be struggling hard to prevent tears He stammered, his face and hands twitched and though unaware of his restlessness he was preoccupied with his inability to hold a conversation or to come into contact with his relatives and former friends

---

[1] A tea masher is employed to pour hot water on much used tea-leaves which have been mashed to a pulp; this is drunk by his fellow workers at short intervals throughout the day It is often done by mental defectives

He had developed a definite character change following head injury, analogous to the character changes that occur at the beginning of any form of dementia, traumatic or otherwise

Case 7—A trooper of 25 was sent in because of eccentric behaviour after a lorry smash 11 months before, the periods of retrograde and post-traumatic amnesia were a few seconds and 4 days respectively There was no history of childhood traits, he was sociable, active, and figured in boxing tournaments from the age of 11, subsequently taking up boxing as a livelihood He took part in many competitions and would often fight four nights in succession Three years before, he had been told not to fight any more because he had developed headaches, would frequently stagger, had become irritable and afraid of the dark and saw double, but he ignored this advice and was knocked out with increasing frequency He reacted fairly well to enlistment and took part in some Army boxing displays, but resented discipline and was afraid of the horses he had to manage He was kept in hospital 4 weeks after his accident and returned to duty but his work was slovenly and he became increasingly irritable, would hit his comrades on the slightest provocation, started to beat his wife and was tearful and remorseful after such episodes He attacked several non commissioned officers, and while under detention awaiting court-martial wandered off into town clad only in trousers He refused to admit that he was in any way ill and resisted violently attempts to bring him to hospital where he heralded his arrival by knocking out the ward master He had bilateral ocular palsies, right nerve deafness and was emotional and tearful With progressive matrices he gave a score of 29 with an uneven scatter and his mental age with the Terman battery was 10½

This patient showed intellectual deterioration and character change before the lorry accident which increased and hastened his mental downfall It should be remembered that boxers often show character abnormalities irrespective of trauma received while boxing, and in some trauma releases and accentuates latent character instability

PSYCHOTIC REACTIONS

There is considerable doubt as to what proportion of these reaction types are psychogenic or physiogenic in origin, but in any case the influence of trauma in producing psychotic symptoms cannot be dismissed as coincidental The trauma may release an endogenous psychotic reaction or it may cause structural damage with resulting symptoms, usually of a manic-depressive or schizophrenic pattern, often after a period of confusion of a Korsakov type The number of previous or subsequent psychotic relapses is no diagnostic criterion because many individuals whether cyclothymic or schizoid may have only one attack in a lifetime, manic-depressives for example may have only one severe depression and if this occurs after a head injury there is no real evidence whether the reaction is due to organic damage or to a psychogenic response to trauma

There were 14 cases in this group, 5 gave histories of previous severe depression and of these 4 responded to trauma with further depression, 1 with a hypomanic phase, 2 had bad family histories Of 8 patients who developed severe depressions none gave a previous history of psychotic or neurotic disturbances, but 3 had parents who had been in mental institutions with manic-depressive disorders The only schizophrenic case had previously been of a schizoid type, asocial and introverted, and after the trauma he passed into a state of negativism and catatonic rigidity which slowly improved in a military mental hospital

Case 8—A corporal of 32 was concussed 5 months before admission when he had 45 minutes retrograde and 3 days post traumatic amnesia He returned to duty after 6 weeks but could not perform his work efficiently, his concentration and memory deteriorated, he had severe headaches, often wept, was irritable, restless and gradually became retarded and self reproachful He gave no history of nervous disorder or noticeable mood swings in himself or his family After continuous narcosis there was a considerable improvement in affect and a reduction in the intensity and frequency of the headaches He was of pyknic build but it was impossible to say if his affective disorder was basically endogenous or exogenous—a response to trauma

Case 9—A private aged 26 had been involved in a lorry smash 6 months before and there were 30 minutes retrograde and 2 days post traumatic amnesia His mother and wife stated that he had numerous bouts of depression, irritability and restlessness, lasting 2–3 weeks at a time before his accident in civil life He reacted well to enlistment and had been free of symptoms for about 10 months when the accident happened He returned to duty after 3 weeks in hospital and had daily headaches, was irritable, restless, solitary, slept poorly and eventually began to knock his head against the wall and tear his hair He was readmitted to hospital on two occasions and altogether had five lumbar punctures with little improvement in his headaches, head-knocking or depression With continuous narcosis and further treatment he improved gradually over a period of two months and was finally headache free and with normal affect

This man gave a history of numerous endogenous manic-depressive mood swings and had reacted to trauma with a further long and severe depression

MIXED CONDITIONS

One of the psychiatric dogmas of the last war held that patients with severe injuries did not develop neurotic reactions; and that these appeared only after mild and trivial trauma This, though largely true, dismissed the problem of denial completely. A number of patients with varying degrees of organic damage refuse to admit that they are ill, or that their physical state or personality is altered in any way, they push their fears into the background and attempt to maintain an appearance of health based on self-deception Such an illusory method of stabilisation is altogether different from a reasoned adjustment to an altered set of circumstances, it is likely to break down because there is much repressed anxiety This refusal to admit a change in the self arises from the wish to remain as near as possible to a picture of the ideal personality built up in phantasies which alter with time but are constant in their desire to maintain a good image of the ego. The latent anxieties and fears arising from the denial of illness are reversible and can give rise to neurotic symptoms when the illusions break upon hard circumstances, so that a mixed picture of organic and psychogenic symptoms results There were 10 patients in this category.

Case 10—A sergeant of 27 had been concussed 7 months before and had a few minutes retrograde and 5 days post-traumatic amnesia He was a month in hospital and was sent back to duty where he had daily headaches, dizziness, numerous blackouts and became afraid of driving He was readmitted to hospital and returned once more to work after 3 weeks where his headaches although slightly improved were still severe He felt he was a nuisance to his unit and worried lest he lose his stripes, but carried on with full duties and after 2 months wandered off in a fugue lasting 11 days during which he walked from Scotland to his home in Yorkshire whence his wife took him once more to hospital

There was no evidence of any previous nervous disorder and he appeared to be a well-integrated person before his accident, his moderately severe head injury was followed by organic residua to which he developed an obsessional fugue as a result of the breakdown of denial

MALINGERERS

The label "malingerer" usually depends as much on the reactions of the physician as those of the patient and there are many variants between the overt liar and the person who eventually believes his own untruths

Case 11—The one malingerer in this series was a psychopath who had about twenty jobs in 7 years of civil life, who resented Army discipline, had frequent headaches accompanying his feelings of rage and resentment, and since a slight head injury 9 months before had complained constantly of headaches, was in four hospitals and was overheard describing his intention to keep on complaining of headaches till he got his discharge

TREATMENT

The treatment of these chronic cases requires perseverance and patience and an atmosphere of reassurance and encouragement For the neurotic and psychotic reaction types every form of psychotherapy can be utilised, but it is important to keep to a systematised and planned attack and not to change rapidly from one form of approach to another Para-military training—that form of military training possible in a hospital—graduated physical exercises, suggestion, explanation of content, narco-analysis and continuous narcosis were forms of therapy adopted according to the type of individual and complaint

Some of those with organic residua were helped by rest in bed followed by graduated head exercises, many who had been initially sent back to duty too early after their injury were benefited by these exercises which were performed first sitting astride a bench which was grasped by the hands, then standing on the ground and finally standing on the bench The head movements consisted largely of rotation, flexion and extension of the head, looking upwards and opening the jaw, &c, and were gradually increased in intensity and rapidity according to the responses of the patient, till the stage of full physical training was reached The movements are performed under the direction of a specially trained PT instructor who encourages the men to feel that despite their encounters with overturned vehicles, hospitals, doctors, lumbar-puncture needles and so on, they are still fundamentally the same, and that their heads have not been either permanently or seriously altered

Repeated lumbar punctures and histamine desensitisation are of little value in reducing the intensity and frequency of headaches Continuous narcosis was tried on one group of 12 patients and insulin sopor treatment on another group of 12, intractable headaches being the most important complaint in both series The object was to make a break in the continuity of symptoms and improve each patient's reaction and tolerance to pain, and also to improve the mild depressions which these patients showed from the start I found that 6 patients were definitely improved by insulin sopor and 4 by continuous narcosis, the others were unchanged Despite all these therapeutic attempts, in a large number of cases the only effective treatment consisted in making the patient realise and adjust himself to his diminished capacity for work, study and pleasure Results are analysed below

—	Cases	Returned to unit	Recommended for discharge
Hysterical reactions	62	34	28
Obsessional reactions	7	2	5
Organic sequelæ	56	19	37
Psychotic reactions	14	2	12
Mixed reactions	10	6	4
Malingerers	1	1	0
Total	150	64	86

It was thought to be as useless to send back to duty patients who would rapidly disintegrate and once more become hospitalised as it was to expect those with frequent traumatic headaches to be able to keep up with the pace of military service, such patients were made as fit as possible for civilian occupation before discharge

PROPHYLAXIS

The prevention of chronic reactions depends largely on efficient handling from the start of illness, and one of the most potent factors in its development is the repeated hospitalisation of patients, each time in a different institution, they spend many months in idleness during which they have ample time to fix their attention on their disabilities

In this command every man who has received a head injury, whatever its severity, now goes forthwith to a head centre where he receives appropriate treatment and is followed up until a decision is made on his disposal, this depends on his reactions to a course of 3 weeks special physical training, including head exercises, through which every patient has to pass, partly so that his response to military training can be assessed and partly as a means of rehabilitation No patient is sent back to duty until he is either symptom-free or has no more than two or three mild headaches every week, those who do not so respond are recommended for discharge from the Army Out of 283 consecutive acute admissions 190 were returned to duty symptom-free, 5 died, 10 were re-categorised and 82 recommended for discharge after treatment, of these 82, 51 were organic and 31 neurotic

SUMMARY

A series of 150 consecutive admissions of Service patients in whom head injury was held responsible for symptoms were investigated

Symptoms included headaches, giddiness, faints, irritability, mild depression, manic-depressive response, impaired memory and concentration, hysterical and epileptic fits, fugues, amnesias, change of character, deterioration of vision, squints, deafness, pareses, sensory disturbances, and impotence

Case-histories are given of 4 patients with neurotic reactions, 3 with organic sequelæ, 2 with psychotic reactions, 1 with mixed symptoms, and 1 psychopathic malingerer

Treatment included psychotherapy, graduated physical exercises, narco-analysis and continuous narcosis, and insulin sopor treatment

Of the whole series of 150, 64 returned to their units and 86 were recommended for discharge from the Army

The following conclusions may be drawn from these cases

Reactions of the personality as a whole should be assessed in order to evaluate the cause of the symptoms and the prognosis Neurological signs are uncommon after head injury and psychiatric and psychometric investigations are therefore important Cases suspected of neurosis or malingering may have developed organic sequelæ after slight head injury Neuropsychiatric control of these cases is desirable, from the onset till the final disposal of the patient, it is useless to send back to duty patients who are not fully recovered The patient who denies his illness may develop neurotic reactions, superimposed on organic symptoms

I wish to thank Dr Flowers for the opportunity to see these cases, and Mr James Hardman for permission to quote the results at his head centre

GIARDIAL INFESTATION WITH STEATORRHŒA

D K. O'DONOVAN,* MD NUI, PH D MCGILL
ASSISTANT PHYSICIAN

JOHN MCGRATH
MD, MSC NUI
BIOCHEMIST AND PATHOLOGIST

S J. BOLAND
MB NUI
RADIOLOGIST

ST VINCENT'S HOSPITAL, DUBLIN

THE following case is the second recorded instance of steatorrhœa associated with giardiasis in Ireland The first was also observed in St Vincent's Hospital, Dublin, and reported by McGrath, O'Farrell and Boland (1940), their patient was a man who had a short history of steatorrhœa with progressive emaciation resulting in death soon after the diagnosis was made from specimens of duodenal contents The chemical analysis and microscopic appearance of the stools was typical of idiopathic steatorrhœa X rays revealed considerable deformity of the mucous-membrane relief of the jejunum and ileum The autopsy findings were widespread destruction of the epithelium of the small intestine, greater even than the X rays suggested, in which *Giardia lamblia* were observed in profusion

CASE-RECORD

This second patient (fig 1), a boy aged 9¼ years, was first seen in February, 1941 The chief complaints were retardation of growth, attacks of diarrhœa off and on for some time, but persistent and severe during the last 6 months, the stools being bulky and pale, a persistent craving for

---

* In receipt of a fellowship from the Irish Medical Research Council

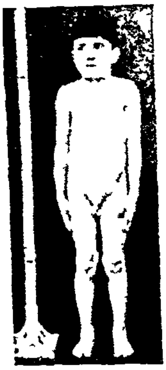

Fig 1—Patient in February, 1941, aged 9½ years Scale of feet

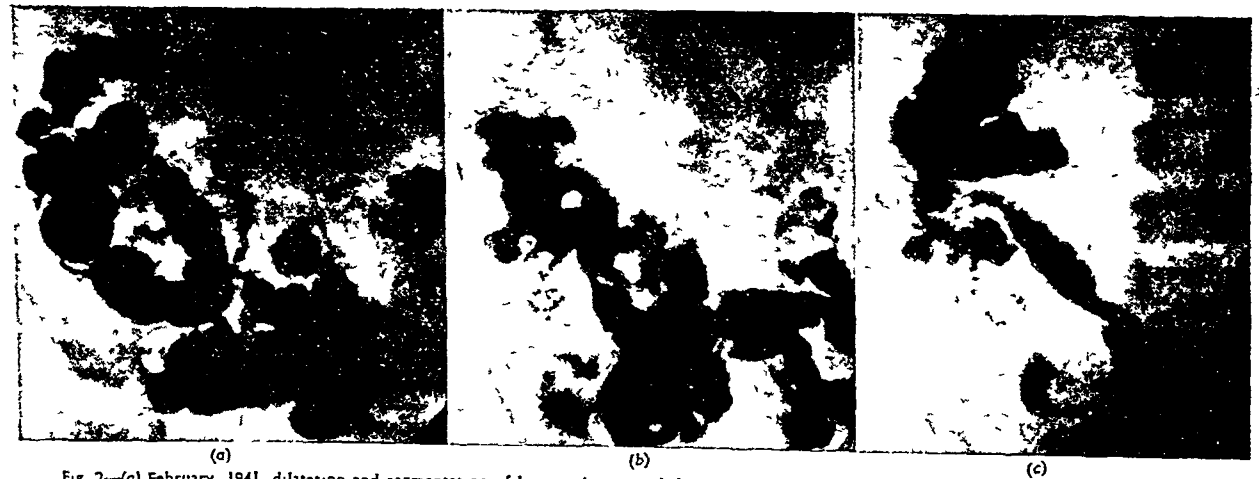
sugar and a relatively enormous appetite, vague abdominal pains, particularly in the left iliac fossa. There were no symptoms of tetany. The family history and previous history were irrelevant except that a brother, two years younger, was taller and stronger.

The patient was undersize and undernourished with slightly protuberant abdomen. His face was wizened and the skin on his legs somewhat dry. Blood-pressure 90/55 mm Hg, pulse-rate 84–120 per min. Serum calcium 10·5 mg per 100 ml and glucose tolerance after 30 g of glucose as follows: fasting level 83 mg, 1 hr 105 mg, 2 hr 91 mg per 100 ml. Blood count: red cells 3,800,000 per c mm, Hb 62% (Haldane), white cells 6400 per c mm (polymorphs 70%, small lymphocytes 21%, large lymphocytes 9%, no eosinophils). The tuberculin skin reaction (Vollmer patch test) was negative. X rays showed deformity of the mucous membrane relief of the lower part of the small intestine (fig 2*a*, *b*), consisting of dilatation, segmentation and absence of normal mucous membrane pattern, the upper loops of jejunum appeared normal. The changes in the small bowel were not so widespread as in the first patient. Slight decalcification of the long bones, bone age normal.

Microscopically the pale-brown stools contained an excess of fat crystals but no excess of fat globules, no parasites were observed during a detailed examination, the benzidine reaction was negative. The stools never contained an excess of mucus except after purgation. Chemical analysis of the fat content of the stools, while on a low fat diet, confirmed the diagnosis of steatorrhœa.

	During infestation	3 weeks after infestation
Fæces wet wt (72 hr bulk sample)	500 g	398 g
Fæces dry wt	150 g	84 g
Fat intake 72 hr	102 g	174 g
Total fat (% of dry fæces)	29·6%	25·2%
Split fat (% of dry fæces)	25·6%	13·7%
Split fat (% of total fæcal fat)	86·2%	54·9%
Total fat excretion	45 g	21 g
Percentage of fat intake excreted	45%	12%

Bearing in mind that the previous giardiasis patient showed no parasites in the fæces, we attempted duodenal intubation, but without success. A severe purgation with two ounces of sodium sulphate was then administered and the liquid stool was examined almost immediately after passage. Its mucous shreds contained numerous encysted forms of *Giardia lamblia*.



(*a*) (*b*) (*c*)

Fig 2—(*a*) February, 1941 dilatation and segmentation of lower jejunum and ileum. (*b*) February 1942 condition unchanged, segmentation still present, (*c*) February 1942, narrowing of terminal ileum and absence of mucous membrane pattern

During the following week the diarrhœa subsided, and thereafter the patient usually passed one brown motion per day, although no specific treatment was given.

Three weeks after the first analysis a second analysis of the stools while on a normal fat diet was within normal limits, as shown in the table. Microscopic examination showed no excess of fat crystals and there were fewer undigested food particles. Five subsequent attempts to find giardia by sulphate purgation failed. The patient was sent home 6 weeks after admission on a diet which included liver and milk, he was taking an iron mixture. Unfortunately this treatment was not adhered to regularly.

By February, 1942, 12 months later, there had been no recurrence of diarrhœa or abdominal pain. There was no other striking clinical improvement. His height was now 45⅝ in—a growth of 1⅝ in in 12 months, whereas the expected growth for this age is about 2 in. He weighed 44 lb. There was still definite anæmia, red cells 4,640,000, Hb 51%, white cells 8000, no eosinophils. Giardia were not observed even after saline purgation. X ray examination of the small intestine showed no change from the first examination (fig 2*b*). Mepacrine hydrochloride ('Atebrin'), which is specific for this parasite, had been given in doses of 0·1 g three times a day for 5 days in January, 1942, and seemed to cause no clinical change in his condition. His appetite was still relatively excessive.

DISCUSSION

The main clinical features of giardial infestation, particularly in children, are steatorrhœa, anæmia, retardation of growth and abdominal pain, but symptoms attributable to inflammation of liver, gall-bladder, duodenum, colon and rectum have also been described (Manson-Bahr 1939, Chopra et al 1939, de Muro 1939, Veghelyi 1940, Nutter et al 1941, Hartman and Kyser 1941). It is a common infestation often without any symptoms in tropical and subtropical climates, and is commoner in children than in adults. Miller (1926) has reported it in England among children suffering from enterocolitis with mild steatorrhœa and mucus.

In view of the autopsy findings reported by McGrath and his colleagues it seemed possible that the symptoms in this patient were due to giardiasis. This hypothesis is supported by the fact that the disappearance of the parasite coincided with the cessation of the steatorrhœa and the abdominal pain. The persistence of the anæmia and the retarded growth must be explained by the local organic lesion in the mucous membrane as revealed by the second X-ray examination.

The points of particular interest in these two cases are that the giardia was not observed in stools passed in the ordinary way, and that the parasite seemed to disorganise the mucous membrane of the small intestine, as indicated by X-ray and autopsy findings. Study of other cases may determine whether supposed idiopathic steatorrhœa sometimes originates through destruction of intestinal epithelium by a transient giardiasis in youth of an intensity midway between the two cases observed here. It seems important, therefore, to collect data on cases of idiopathic steatorrhœa soon after the first appearance of symptoms. The relationship to idiopathic steatorrhœa is also suggested by the X-ray findings in the patient described here, which resemble those reported by Kantor (1939) in cases diagnosed as idiopathic steatorrhœa, in our patient, however, the changes were confined to the lower portion of the small bowel. Abnormal X-ray findings indicating atony of the small bowel have been reported in malnutrition and avitaminosis (Kiefer 1939), but our patient suffered from defective absorption rather than defective intake

Finally, it is possible that patients suffering from dwarfism and malnutrition without intestinal symptoms, but showing some deformity of the lower small intestine as judged by the X-ray findings may be suffering from the sequelæ of giardiasis We have had one such patient under observation in whom no pathogenic parasites were found

SUMMARY

In a case of giardiasis in a boy the symptoms and findings resembled those of idiopathic steatorrhœa The parasite was found in the stools only after a severe saline purgation, after which the steatorrhœa and abdominal pains disappeared, and the parasite was not subsequently observed X-ray findings which were unaltered a year later indicated a persistent abnormality of the epithelium of the small intestine

Some cases of so-called idiopathic steatorrhœa may have been due in the first place to injury of the intestinal epithelium by a transient giardial infestation

SOLUBLE PHENYTOIN IN EPILEPSY

GLADYS M TULLIDGE
M.D. LOND
ASSISTANT MEDICAL OFFICER

J TYLOR FOX
M D CAMB, D P M
MEDICAL SUPERINTENDENT

LINGFIELD EPILEPTIC COLONY

ONE point emerges from the considerable literature which has grown up about the use of soluble phenytoin (sodium diphenylhydantoinate) in epilepsy—that the effective therapeutic dose is very near the toxic dose In other words, if the patient has enough to stop his fits he runs a considerable risk of showing toxic signs, often of a fairly serious nature Another disadvantage of the drug is its expense The clinician is therefore entitled to ask whether it is established that soluble phenytoin is so much more effective than, say, phenobarbitone or the bromides as to justify the risks and expense Such justification, he might argue, would only be found if fits were completely arrested or drastically reduced, slight or moderate fit reduction would be bought at too high a price

During the past 3 years we have given soluble phenytoin to over 130 patients at Lingfield, but in attempting to give an answer to the clinician's question we decided to consider only those whose fit incidence under previous treatment here was known, and in whom the dose of soluble phenytoin had been increased until either the fits were completely or almost completely stopped, or until toxic manifestations of so serious a nature had appeared that withdrawal or reduction of the drug became necessary Thus we had to discard the records of patients who were taking soluble phenytoin on admission, who were receiving phenobarbitone at the same time, or who have not yet been worked up to the optimum therapeutic dose There remained 63 cases whose previous fit incidence, usually over a twelve-month period, was known, and who had reached either the optimum therapeutic or the toxic dose The age-incidence of this group, which contained 38 males and 25 females, was as follows 6 aged 5–10; 44 aged 11–15, 8 aged 16–20, 5 over 20 The average intelligence quotient was 80 It was therefore a group of adolescents, normal, or only moderately retarded in intelligence, this must be borne in mind, since different results might be found in older patients with more stabilised nervous systems and more confirmed fit habits

In all cases bromides, usually in doses of gr 20–30 a day, and phenobarbitone, usually gr 2 a day, had proved of little or no value Dosage of soluble phenytoin was started with gr 1½ tablet two or three times a according to age, given with food, and was increased one tablet a day at intervals determined by the fit incidence and other considerations until the cessation of fits or the appearance of untoward symptoms called a halt, 4 patients never got beyond two tablets a day, 30 stopped at three, 24 reached four, 4 reached five and only 1 achieved the maximum dose of six

FIT INCIDENCE

In considering fit incidence under soluble phenytoin only the incidence under the maximum dose (i e, the effective dose or the toxic dose) will be taken into account. In many cases the period during which this dose was administered was cut short by the appearance of toxic signs, and it would be misleading to place any value on fit figures over a period of a few days or weeks We therefore decided, in estimating the effect of the drug on fit incidence to ignore all those cases—20 in number—where the maximum dose could not be maintained for more than two months The remaining 43 cases had taken the maximum dose for 2 to 20 months, the average period being 5½ months In counting fits any which occurred in the first few days of maximum-dose administration were ignored During this time the effect of the increased dose had perhaps not got well under way, and in a few cases at the beginning of treatment the attacks might be due to withdrawal of phenobarbitone With this proviso, it was found that 24 of the 43 patients were completely clear, and 16 almost completely clear of fits, while only in 3 patients were the fits either increased, unaltered or only moderately decreased in number When it is remembered that these were all cases which had proved resistant to previous medication, the figures show that soluble phenytoin is a most powderful anticonvulsant drug

The fit picture, however, is not quite so rosy as these figures imply, for among the 20 cases who had the maximum dose for less than 2 months there were 8 in which improvement was slight or absent Of the total of 11 recalcitrant cases, 4 had major fits, 5 had frequent petit mal and one had major fits which under soluble phenytoin were partly replaced by attacks of slighter and varying severity The other patient was a boy who judged by the accepted criteria was a typical case of pyknolepsy extending over many years. With soluble phenytoin the petit mal ceased, but he had a major fit

In only 4 of the 63 cases was soluble phenytoin withdrawn on account of failure to control fits One was the boy already mentioned, whose pyknoleptic attacks were replaced by a major fit, one was a young man whose attacks of petit mal were aggravated by the treatment, and the other 2 had major fits which were becoming more frequent with increasing dosage

If we group together major fits and attacks characterised by loss of consciousness lasting for more than a few seconds and accompanied by local or general convulsions (incomplete major fits), we find that in 72% of all cases these fits were entirely arrested by soluble phenytoin, in 84% psychomotor attacks were similarly stopped, whereas with the one exception mentioned in no case was there arrest of momentary attacks of petit mal (absences) In cases of petit mal the drug was pushed until toxic manifestations appeared

A pertinent question is how far arrest of fits is likely to be maintained We have not sufficiently long experience to answer this question Tolerance, as evidenced by return of fits, may occur after weeks or months of freedom, and a further increase of dose may be required But a review of our cases shows that tolerance is definitely less common than with phenobarbitone It has been reported that a fit-free period on soluble phenytoin may be broken by a rush of fits, rather than by the gradual return of attacks characteristic of phenobarbitone tolerance Our records lend some confirmation to these reports In 2 cases in this series recurrence was manifested by a burst of attacks, whereas such a sequence of events has only occurred once in 24 years experience with phenobarbitone

TOXIC MANIFESTATIONS

The margin between an effective therapeutic dose and a toxic dose is always small with soluble phenytoin In many cases the doses are identical In no less than 24 of the 63 cases the drug had to be stopped or reduced on account of serious toxic manifestations. In 17 of these the fits gave every promise of complete, or nearly complete, control.

The toxic manifestations are readily classified under three heads: skin troubles, 3 cases; mental changes, 3 cases; neurological disorders, 18 cases.

Skin troubles.—Three patients were taken off soluble phenytoin on account of skin manifestations; 2 were boys who had been taking three tablets a day for 4 weeks, one was a girl taking two tablets for 12 days. In a fourth case three tablets caused a rash in a boy after 10 days but as there was no pyrexia the drug was continued and on the third day the rash faded. None of these children showed any other signs or symptoms of toxicity from soluble phenytoin. In 3 there was malaise and a moderate pyrexia, the highest temperature recorded being 102° F on the second day. On first appearance 3 cases resembled measles; the face was bright red with puffiness under the eyes; the trunk showed a bright red discrete maculopapular eruption (not present at the back of the neck or ears) which tended to coalesce and become confluent forming large erythematous areas. In one case there was no discrete rash but confluent patches occurring in a hemiplegic arm and leg. The severity of the symptoms and the height of the rash appeared on the second or third day, after which it began to fade and had almost disappeared by the end of a week. In 2 cases the rash reappeared in a mild form a month after treatment had been stopped. Recorded cases of general exfoliative dermatitis following soluble phenytoin rashes influenced us in our decision to stop the drug when the skin lesions appeared.

Mental changes in epileptics following any particular form of treatment are difficult to assess. None of our patients were insane, a few were high-grade mental defectives, but quite a number showed in varying degree that instability, sensitiveness and inadaptability which are regarded as characteristic of the epileptic temperament. Periodicity is often a prominent feature of these manifestations, and their increase or decrease at any time may have little or no relation to any particular form of treatment. Further, all the patients treated were fairly severe cases of epilepsy with frequent attacks. To stop their fits suddenly in mid career was a drastic thing to do, and the cessation was likely to give rise to mental change, beneficial or the reverse, apart from any specific action of the drug. Many, possibly the majority, of our patients were brighter and happier with an effective dose of soluble phenytoin because they realised that their fits had stopped and their future was more hopeful. Some cases showed dramatic improvement. A girl of 14 was mischievous, restless, acquisitive, an eater of refuse, incontinent by day and night and subject to epileptic fits in very large numbers. Soluble phenytoin medication was followed at once by an absolute arrest of fits, and an extraordinarily rapid disappearance of all her unpleasant characteristics. The freedom from fits and improvement in behaviour have now lasted for nearly a year. In some patients, on the other hand, the cessation of attacks was followed by a period of increased irritability with hypersensitiveness, quarrelsomeness and even violence. In 7 of the 63 cases this condition was noted, but was not severe enough to call for withdrawal of soluble phenytoin, but in 3 cases the treatment had to be abandoned; 2 of these were young adults with a long history of frequent fits; one of them was confused as well as violent, and the other showed confusion with delusions. The third was a boy of 15 whose natural irritability increased to a violence which made him dangerous to others. In all 3 cases, the mental symptoms appeared when the dose had been increased to four tablets a day. These confirm a belief we have long held that there is a small group of epileptics who should be allowed at all costs to continue having their fits. In only one of the 63 cases was there any report that soluble phenytoin produced drowsiness.

No general statement can therefore be made about the effect of soluble phenytoin on the mind. Our experience leads us to believe that mental changes following its use are probably due to drastic interference with the fit incidence rather than to any specific effect of the drug itself.

Neurological disorders are by far the most important, and also the commonest, manifestations of toxicity due to soluble phenytoin. In 18 of our series the neurological picture was so grave that the drug had to be reduced or stopped. There were five principal neurological signs of overdosage and in cases which called for action these signs seldom occurred singly. In 6 cases they made their appearance with only three soluble phenytoin tablets a day, in 9 cases with four tablets; in 2 cases with five; and in 1 case with six tablets. The average duration of the maximum dose before neurological manifestation necessitated withdrawal was 6 weeks. It ranged from 3 days to 32 weeks—a fact which shows that supervision must never be allowed to relax. In order of frequency the signs were: nystagmus, 14; ataxia, 10; tremors, 9; diplopia, 6; vomiting, 6 cases. None of these manifestations were confined to the 18 cases under review; they were also found singly or in groups in several of the other 45 patients but not in a serious degree. The first and most frequent sign of toxicity is undoubtedly nystagmus. Slight to-and-fro movements of the eyes on extreme lateral deviation, in a patient in whom this was absent before medication, is a warning that his nervous system is beginning to feel the strain of soluble phenytoin. Such mild lateral nystagmus was often seen in our series; in the more advanced cases gross nystagmus, both horizontal and vertical, was seen.

Patients with fully developed ataxia presented a grievous picture that could not be overlooked. Cases of tremor varied from fine tremor of the extended hands to irregular coarse movements that bordered on myoclonus. Rarely were the tremors of sufficient significance by themselves to call for interference. Diplopia is a subjective symptom, and since leading questions to children were, we felt, better avoided we think it probable that the number who had diplopia was much larger than the number recorded. It might well rank with nystagmus as one of the cardinal signs of soluble phenytoin intoxication. It was seldom accompanied by a demonstrable squint. We decided to include vomiting among the neurological manifestations only after a careful review of case-histories. An occasional vomit or a complaint of nausea was common in our patients. In many cases the complaint could be ignored and there was no recurrence; in others a small reduction of dose for a day or two was effective. In the more serious cases, where vomiting was persistent it was invariably accompanied by fairly severe neurological manifestations. We therefore conclude that it is more reasonable to regard it as evidence of disorder in the central nervous system than of gastric irritation. Other neurological signs, such as slurred speech, myoclonus, or symptoms such as dizziness, headache or blurred vision were met with in isolated cases, but on analysis the five which we have stressed stand out as the distinctive features of soluble phenytoin intoxication.

A reassuring observation is that all the toxic manifestations recorded above, with the exception of the skin lesions, invariably disappear within 2–3 days if the drug is stopped.

Gums.—Simple hyperplasia of the gums has often been noted, and is a sign that must be looked for, since the patients do not complain of it. Its detection is not worth recording unless a note has been made of the gum condition before soluble phenytoxin was started. We noted it in 9 of our 63 cases, and in none did it assume such formidable proportions as to call for withdrawal of the drug.

COMBINED MEDICATION

If soluble phenytoin, given in optimum therapeutic doses, is so often toxic, why not give it in somewhat smaller doses with phenobarbitone? Some authors have indeed written of the synergistic action of the two drugs. Our experience of this combined medication has not been large enough to justify a reply to the question, but neither has it been very encouraging. In any case careful observation over long periods with the drugs in varying proportions would be required before any conclusions could be reached.

SUMMARY

An attempt has been made to answer the question whether soluble phenytoin is such a powerful anticonvulsant that its use in epilepsy is justified in spite of the risks it entails. The answer is in the affirmative. By gradually increasing the dose fits can be drastically reduced or completely stopped in most patients, but with the effective therapeutic dose grave toxic signs calling for withdrawal will occur in at least a third of the cases From this it follows that soluble phenytoin should never be prescribed unless phenobarbitone and the bromides have first been given a thorough trial, and that, if clinically effective doses are aimed at, every case under soluble phenytoin demands close and continuous supervision

EXTENSIVE AIRSCREW INJURIES

John Howkins
M S LOND , F R C S
SQUADRON LEADER, R A F V R

Geoffrey Wooler
M B CAMB , F R C S
CAPTAIN R A M C

THIS case is reported as an example of extensive non-fatal injury to the thorax and to show the kind of damage that a revolving airscrew can inflict on a man

CASE-RECORD

The patient, AB, aged 18, joined the RAF as an aircraft apprentice and became a fitter in June, 1941 On June 18, 1941, at 10 40 A M , the captain of a Blenheim aircraft finished running up his engines and gave the signal to remove the chocks under the wheels AB failed to remove the port chock at his first attempt and in swinging his body round to get better leverage was caught by the blades of the port airscrew The accident took place at the periphery of a large aerodrome, and it was 20 min before a runner could fetch the ambulance and the medical officer on duty When first examined, AB was pale, sweating and with a weak pulse of 100 per min His extensive injuries were dressed by the simplest possible first aid compression dressings and he was transferred to the infirmary, 10 min drive away Bleeding was surprisingly slight Oxygen was given during the journey, and though his pulse rate rose to 120 his general condition deteriorated little When admitted he was immediately transfused with 2 pints of whole stored blood, but no attempt was made to disturb his dressings When seen by one of us (J H) a little over an hour after his accident, he was conscious, severely shocked, with a pulse rate of 130 His respirations were much embarrassed and he was cyanosed He had a sucking pneumothorax of the right chest, though this was effectively controlled by his dressing

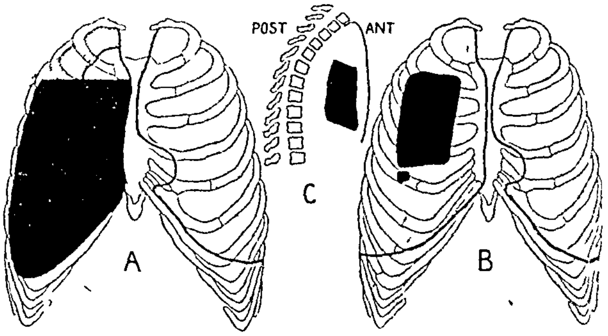
His right arm was hanging by his brachial plexus and brachial artery, a small flap of skin and part of the biceps , all extensor muscles and the bone were severed completely The right radial pulse was impalpable A large gash starting behind the right clavicle had severed ribs 3–9 inclusive The tip of the airscrew had lacerated all three lobes of the right lung posteriorly to an average depth of 1 in , there was continuous bleeding from the lung, but little from the parietes A third gash passed from the superior medial angle of the right scapula obliquely across his spine down to the level of his 8th left rib This gash had cut through the spines of his upper dorsal vertebræ down to the dura mater of the cord without opening it—a sort of fortuitous laminectomy A fourth gash, about 6 in long, extended from the middle of the spine of the left scapula down to the left posterior axillary fold, cutting the superficial parts of the supraspinatus and infraspinatus on the left and nicking the spine of the left scapula

OPERATION

We decided to operate, though realising that any surgical interference would probably kill him, because of the persistent and progressive hæmorrhage from his right lung. He was now given 2 pints of plasma and routine anti shock treatment

Just before operation, at 3 P M , his pulse rate was 140, respiration rate about 50 and systolic blood pressure 50 mm Hg No premedication was given and anæsthesia was induced with 2 c cm of a 5% ‘Pentothal Sodium’ (Abbott) solution This was injected directly into the rubber tubing of the blood drip, previously put up Oral intubation was then carried out by direct vision and anæsthesia was maintained with a mixture of cyclopropane and nitrous oxide using the carbon dioxide absorption technique with a ‘Circle’ absorber[1] After induction respiration failed completely and continuous artificial respiration was established by intermittent positive pressure on the rebreathing bag No effort to bring back natural respiration was made until the end of the operation During the operation the blood pressure was too low for any adequate record to be made, though the beating of the heart in the chest could be observed At the close of the operation, however, a reading of 60 mm Hg, systolic, was obtained The pulse rate remained at about 160 per min throughout, often being imperceptible in the temporal artery He was given a pint of whole blood during the operation

The bleeding came from the lung and not the chest wall—the reverse of the usual finding An ample thoracotomy had been provided by the airscrew No attempt was made at a classical excision and debridement of the wounds, the irregularities of the fractured ribs merely being trimmed with rib shears Hæmorrhage from each separate lobe of the lung was controlled by both interrupted and mattress sutures of catgut, put in with a large round-bodied needle There was no hæmatoma , an air screw makes a clean incised wound. When the pleural cavity was quite dry, the wound of the thorax was closed without drainage, after being liberally sprinkled with sulphanilamide powder This lack of drainage was a mistake , it would have been better to put in an intercostal tube, which of course would have had to be closed if inserted at this stage The chest wall was sutured with interrupted catgut through pleura and muscles and interrupted silkworm gut through the skin The other gashes of the back were also closed without drainage and the right arm was disarticulated at the shoulder joint, because the blood supply was thought to be so jeopardised that conservative treatment would be mischievous At the end of operation his condition was a little better and he was given a further 2 pints of whole blood, making 5 pints of blood and 2 pints of plasma in all



Tracings of radiograms A, four weeks after accident, showing complete blackout to second rib B and C pleurogram eight weeks after accident, showing apical empyema

SUBSEQUENT PROGRESS

Convalescence was stormy The day after operation his pulse rate fell to 100, respiration to 22, and his temperature was normal His wounds were left untouched for a week The superficial wounds of his back healed by primary union, but his thoracotomy wound became mildly infected as did his amputation wound On the 8th postoperative day he developed a swinging temperature in the neighbourhood of 103° F which persisted for 3 weeks Serial X rays of his chest were taken every week The first, a week after operation, showed that his right lung had re expanded and that the pneumothorax had been absorbed, but it soon became apparent that an empyema was developing On July 10, 22 days after operation, his temperature started to go up and he became very toxic X rays showed what appeared to be a simple right empyema with a fluid level reaching the 4th rib behind Aspiration was attempted, but only 20 c cm of pus were withdrawn from the 2nd space anteriorly Below this level, posteriorly and laterally, the needle went into lung A diagnosis was made of apical empyema with pneumonitis of the lung

On July 12 a plain X ray (A in figure) showed a complete blackout up to the 2nd rib, suggesting a right pyothorax, this proved to be a right apical empyema, with pneumonitis and possibly collapse and infection of the pleural cavity and lung below A more penetrating film was taken but failed to show any more detail except of the bony structure He was too ill at this time for a rib resection, and the lowest limit of the empyema had not been defined On July 17 he was transferred by ambulance, bearing the journey well On July 19 Mr Price Thomas inserted into the 2nd space anteriorly an intercostal tube connected to the usual closed water seal drainage bottle , this drained about 2 oz of pus each day On Aug 6 a pleurogram showed an apical empyema lying mainly in front (B and C in figure). On Aug. 9 a rib resection was performed at the lowest limit of the cavity (5th rib, anterior axillary line). A wide bore tube connected to a closed drainage bottle was inserted. The patient gradually improved. He was encouraged to do the active inspiratory exercises outlined by MacMahon[2] and to exercise his muscles by sitting up in bed and bending from side to side. These exercises require the help of an operator who fixes the chest wall with his hands, as required, thus enabling the patient to expand different parts of the lung in turn.

---

[1] Made by Medical and Industrial Equipment, Ltd

He was repeatedly screened and pleurograms were taken to make certain that the tube was in the correct position and that there was no fluid level present. The upper lobe was seen to expand gradually and fill the empyema cavity. The lower part of the lung gradually cleared. Closed drainage was continued until the discharge became too small to measure. On Nov. 17 another pleurogram showed only a very small cavity inside the chest, holding about 3 c.cm. of iodised oil. Closed drainage was discontinued and a smaller open tube was inserted. This was not to be removed until the empyema cavity had completely closed. By Nov. 20 the right lung had cleared completely except for two small opacities in the mid-zone which appeared to be pleural. He had no cough and no sputum and felt well. He was going out for short walks and had gained a stone in a month. His wounds were dressed with tulle gras (Optrex) and they healed without skin grafting; saline compresses were applied at intervals to prevent excessive granulations. He had no neurological signs resulting from the laminectomy.

DISCUSSION

In this case, sucking of the extensive chest wound was controlled by the original dressing. The decision to operate despite his grave condition was made because of the presence of active hæmorrhage—not, as commonly happens, from the chest wall but from the lungs. Local anæsthesia was ruled out by the extent of his injuries. He had been given 2 pints of blood and 2 pints of serum soon after admission to hospital, but it seemed unwise to push large amounts of fluid into his already failing cardiovascular system until after the operation; he was given a further pint of blood by the drip method during the operation itself. Respiration failed during induction, but since natural respiration would probably have been paradoxical, no attempt was made to restore it. Instead, controlled respiration, as described by Nosworthy,[3] was maintained by compressing the rebreathing bag, and anæsthesia was kept at a level just deep enough to inhibit natural respiration. The chest should have been drained by a closed intercostal tube at this stage; had this been done he might have escaped the apical empyema which subsequently developed. This empyema was drained successfully and its progress was carefully controlled up to complete healing. Breathing exercises to encourage active movements of the injured lung were an essential part of the treatment.

SUMMARY

An airscrew accident is reported, with severe injuries of the right arm and laceration of all three lobes of the right lung. The lung was sutured, the chest closed without drainage and the right arm disarticulated at the shoulder-joint. The patient developed a massive infection of the right lung and an apical empyema; this was drained and the lung condition has resolved. He recovered completely, and his retention in the Service is being considered.

We wish to thank Flight-Lieutenant Fenwick, R.A.F.V.R., for details of the accident; Squadron-Leader B. G. B. Lucas for details of the anæsthesia; Dr. Geoffrey Jones, medical superintendent of Bridgend Infirmary, for his cooperation; and Mr. Price Thomas under whose care the patient finally recovered.

MEDICO-LEGAL SOCIETY.—The annual general meeting will be held at 26, Portland Place, London, W.1, on Thursday, July 16th, at 5.15 P.M. Afterwards Dr. G. Roche Lynch will deliver his presidential address on poisons and poisoning.

Medical Societies

BRITISH ORTHOPÆDIC ASSOCIATION

DELAYED UNION OF FRACTURES

AT a meeting held in Liverpool on May 29 and 30, under the presidency of Mr. G. R. GIRDLESTONE (Oxford) a discussion was held on delayed union of fractures.

Most speakers remarked on the impression generally held that delay in union is commoner than formerly; many of them mentioned the difficulties of the statistical approach both in deciding on a standard of "union" for considering the time factor, and in comparing fractures of the same bone due to different types of violence. There was agreement about the evils of late reduction, of distraction and of infection.

Mr. G. PERKINS (Roehampton) differentiated between "union," when the fracture was solid, and "consolidation" when this had progressed to the state of ability to withstand normal stresses. He emphasised the importance of functional restoration and the need for muscular activity from the outset of treatment.

Mr. R. WATSON-JONES (Liverpool) and Squadron-Leader W. D. COLTART, presented a detailed analysis of 500 shaft fractures of the femur and tibia treated in R.A.F. orthopædic units. The most important factors responsible for delay in the union of these fractures had been (*a*) infection, which trebled the union time; (*b*) distraction of the fragments by excessive skeletal traction, which caused very definite indolence of the fractured surfaces and doubled the union time; (*c*) delayed reduction, late re-manipulation and in the case of the femur late bowing or re-fracture, which almost doubled the union time. In the absence of these delaying influences, fractures united firmly enough for the removal of splints and plaster in an average of 14 weeks. Union to clinical tests had often been present earlier than this, but immobilisation had been continued in walking plasters until the stage of radiographic consolidation. The early resumption of weight-bearing in a walking plaster had been proved to be a delaying factor in cases where minor angulation remained; the weight-bearing tended to increase the angulation momentarily, and thereby distract the fractured surfaces on the open side of the fracture. If it was recognised that union had been delayed by infection, distraction, late re-manipulation, &c., and the period of plaster immobilisation was extended accordingly, these factors were responsible only for slow union and not for non-union. In this series, where complete and uninterrupted immobilisation had been maintained, though in 8 cases early bone-grafting had been performed to accelerate the rate of repair, there was not a single case of sclerosis of the fractured surfaces and established non-union, despite a high proportion of grossly contaminated and infected fractures. Ten per cent. of the cases had been invalided; ninety per cent. returned to duty.

Mr. B. H. BURNS (London) believed that the advantage of the more accurate anatomical position maintained in the modern unpadded plaster cast was possibly counterbalanced by the longer time that appeared to be taken in reaching union. Well-planned open reduction in selected cases offered perfect anatomical restoration with greater freedom of the soft parts.

Prof. HARLAN WILSON (U.S.A.) believed that the type of initial violence might account for the greater time taken by motor-cycle injuries to heal, where speed of impact was noteworthy. He believed that damage to the vascular supply of bone had a great bearing on the time of healing. He remarked on the frequency of delayed union in cases of multiple fracture, which made greater demands on the body's osteogenic functions than single injuries. In his experience the Roger Anderson method of treatment gave the same time of fracture healing as other methods.

Major A. W. M. WHITE (R.C.A.M.C., Toronto) believed that the factors most likely to affect the rate of union were apposition of fracture surfaces and complete and continuous immobilisation. In his survey of 120 cases of fractured tibia, reduction was considered adequate when it was radiologically estimated that 75% of the fracture surfaces were in apposition. In 51 well reduced and immobilised legs the average time for union was 4½ months; in 13 inadequately reduced or poorly immobilised cases it was 8¼ months Bone-grafting had resulted in union in 96% of the cases, but rehabilitation seemed to take longer than in cases uniting without operation

Mr D L GRIFFITHS (Manchester) made a determined plea for inquiry by statistical methods He had submitted 249 cases of fracture of both bones of the leg with displacement to such inquiry, and had arrived at four definite conclusions—open fractures healed more slowly than closed fractures, the two forming distinct groups, direct violence, severe violence, and inadequate apposition of fragments, were all delaying factors Figures indicated that only the grosser errors of treatment were important in delaying union

Mr F W HOLDSWORTH (Sheffield), in a study of 399 cases of fracture of the leg, treated throughout by his own team, found that 349 returned to their own work and 35 to modified work, 15 had very poor function Of 303 adults, 102 compound fractures united in an average of 16½ weeks (the longest were 28 weeks in 4 cases), the remaining closed fractures united in an average of 13 weeks He urged concentration on the quality of end-results rather than on the time taken to reach them Continuity of treatment by one unit was the essential requirement He and other speakers deprecated the late reduction occasioned by the slow movement of patients from one hospital to another

Dietetic factors were discussed by Mr R I STIRLING (Edinburgh), with particular reference to the important part played by vitamin C

REHABILITATION

On Friday afternoon, May 29, the association visited the RAF Rehabilitation Centre at Hoylake, by kind permission of the Air Ministry, and members were conducted round the gymnasium, playing fields, swimming pool and so on Mr WATSON-JONES gave a clinical demonstration at which he stressed the importance of carefully graduated muscle exercises, carried out initially under the guidance of the medical officer and later in the gymnasium under the control of a group of physical-training instructors and masseuses, and the value of various outdoor games in which the competitive team spirit was encouraged Flight-Lieutenant HAROLD CANTOR described the working of the centre and the importance of the patient's treatment being kept under the close supervision of a medical officer at all stages Finally Squadron-Leader DAWES, the commanding officer, said how important it was to recreate mental and moral fibre in addition to restoring patients to full physical fitness

AMPUTATIONS

On the second day of the meeting a discussion was held on amputations, based on the different views held by surgeons in Canada and Great Britain The former attitude was stated by Dr A B LE MESURIER of Toronto The Canadian preference for end-bearing stumps for leg amputations was founded on the excellent results and superiority of this type, compared with those depending on lateral bearing in the socket of an artificial limb He was surprised to find Syme's amputation so universally condemned in Britain

Dr R D L KELHAM (Roehampton) explained the views of the limb-fitting surgeons for the Ministry of Pensions, remarking on the large number of Syme's amputations performed in the last war which had been re-amputated at a higher level Many of these patients had been unable to tolerate end-bearing for more than eight years, and of those which had had re-amputation performed not one had failed to express his gratitude at being provided with a stump which gave complete confidence A particular advantage was the better appearance of the limb, which was of importance to a woman

Mr W A COCHRANE (Edinburgh) pleaded for further consideration by British surgeons of the advantage of Syme's amputation

NUTRITION OF EXPECTANT AND NURSING MOTHERS

INTERIM REPORT OF THE PEOPLE'S LEAGUE OF HEALTH

THE People's League of Health appointed a special committee * in July, 1935, to consider the effect of the nutrition of expectant and nursing mothers on maternal and infant mortality and morbidity The committee has now completed a survey which involved the study of the records of 5022 women and which the committee believes to be more comprehensive than any similar investigation previously carried out The league had the cooperation of 10 London hospitals East End Maternity Hospital, Hammersmith Hospital (LCC), Mother's Hospital (Salvation Army), Queen Charlotte's Hospital, Queen Mary's Maternity Home, Royal Free Hospital, St Mary Abbot's Hospital (LCC), St Thomas's Hospital, Thorpe Coombe Maternity Hospital, and University College Hospital Three commercial firms—Messrs Vitamins Ltd, Crookes Laboratories and Roche Products Ltd —supplied the vitamin and mineral elements required, free of charge

The main investigation, which was carried out from March, 1938, to the end of 1939, was planned to show whether additions of vitamins and minerals to the food would benefit the course of pregnancy and labour and the newborn child In order to obtain some information concerning the type of diet consumed by the group of women to be studied, an inquiry was made among expectant mothers attending four of the hospitals which collaborated in the test, these patients included some of the women enrolled in the investigation It was not possible to make a detailed dietary survey, but nearly 1000 women filled in questionnaires recording the food they had eaten during a week This was at best a rough and ready method of assessing food consumption, but there were good reasons for believing that it would give some evidence of the nutritional level of the women during the experimental period A scoring system was adopted by which arbitrary values were given to express the daily consumption of the more important foodstuffs, such as milk, butter, wholemeal bread, fresh vegetables, fatty fish, fruit, eggs, &c By making a sum of the weekly score for appropriate foods, approximate estimates could be made of the intakes of first-class protein, vitamins, minerals, &c, while from a general summation a picture of the diet as a whole was obtained This procedure was sufficient to reveal any well-marked deficiencies in the diet A somewhat similar scoring system has recently been found of great practical utility in nutritional investigations in Toronto

Analysis of the records showed that, in general, there was no well-marked deficiency of first-class protein among any of the women answering the questionnaires As regards minerals, a shortage of calcium was noted in about 70% of the women, most of whom were consuming insufficient milk and cheese Iron deficiency was even more serious, only 2% of the women having a satisfactory intake As regards vitamins, the deficiency of A was the most common, this being anticipated from comparison with other pre war data Rather more than half of the women were taking less vitamin A than they required Generally speaking the diets were not badly defective in vitamin B_1, but nearly half the women were not obtaining as high an intake as was really desirable Vitamin C shortage also affected about half the women, but once again the deficiency was not nearly so great as had been expected The general impression was that the women were on the average better nourished than had been expected from previous surveys of comparable groups of the ordinary population Many of the women were clearly following advice given at the antenatal centres, and fresh fruit and eggs frequently entered into their daily diet The same was true of milk The women said they were taking these foods especially because they had been advised that the health of their babies would thereby be improved There were, however, instances in which the dietaries were grossly defective

---

* The executive committee included nine fellows of the Royal College of Obstetricians and Gynæcologists Prof JAMES YOUNG (British Postgraduate Medical School), chairman, Miss MARGARET BASDEN (Mothers' Hospital, Salvation Army) Prof. F J BROWNE (University College Hospital), Prof AMY FLEMING (Royal Free Hospital), Dame LOUISE MCILROY (Thorpe Coombe Maternity Hospital), W C W NIXON (St Mary Abbots, Hospital, LCC) medical secretary, W H F OXLEY (East End Maternity Hospital), L CARNAC RIVETT (Queen Charlotte's Hospital) and JAMES WYATT (St Thomas's Hospital), and the following H DAVIS PHD, PHC (pharmacist UCH), Prof J C DRUMMOND (professor of biochemistry, University College, London), Miss LETITIA FAIRFIELD, MD, (senior medical officer, LCC), W T RUSSELL, FSS (statistician, London School of Hygiene), Miss JEAN WISHART SRN (Queen Mary's Maternity Home) and Miss OLGA NETHERSOLE (founder and honorary organiser, People's League of Health)

The committee next decided on the amounts of vitamins and minerals required to make up the deficiencies noted The daily supplements used for the experiment were

Saccharated iron carbonate, gr 18 (1 2 g), equivalent to 0 26 g ferrous iron

Calcium lactate, gr 30 (2 g) equivalent to 0 26 g calcium

Minute quantities of iodine, manganese and copper

Adsorbate of vitamin B_1 containing all factors of the B complex (B_1 content standardised at 200 I U per g) gr 15 (1 g)

Vitamin C (ascorbic acid), 100 mg

Halibut liver oil (vitamin A, 52,000 I U per g and vitamin D 2500 I U per g), min 6 (0 36 g)

In each hospital the women enrolled at the antenatal clinic were divided into two main groups by placing them alternately on separate lists The women in one group received the supplements, while those in the other were kept as controls Within each of these groups the women were further classified into primigravidæ and multiparæ These two groups were again subdivided into women under 25, between 25 and 30, and over 30 years All women who were not in good health or whose delivery was expected in less than 16 weeks were excluded from the experiment

The groups of important records thus obtained have been analysed by Mr W T Russell, the statistical member of the committee, and his assistants, but the extent of the material collected and the exigencies of the war have made it impossible to prepare a full report at present In view, however, of the importance of certain facts which have emerged it has been decided to issue this preliminary report

TOXÆMIA OF PREGNANCY

At the beginning of the research it was decided to regard as toxæmic (*a*) women who exhibited hypertension (a systolic blood-pressure of or above 140 mm Hg or a diastolic pressure of or above 90 mm Hg) with or without albuminuria, œdema, &c , and (*b*) women who had no hypertension but in whom the diagnosis was based on albuminuria In the 1530 primigravidæ who received the supplementary diet the toxæmia-rate on this standard was 27 1%, while in 1512 primigravidæ who did not receive the supplementary diet the rate was 31 7%, the difference being 4 6 ± 1 7% This result was due to the dominating influence of the women aged 25–30, in whom the difference was 7 7 ± 2 6% At the younger and older ages the difference, although still favouring the treated groups, was statistically unimportant In multiparæ there was no difference between the two groups, the incidence of toxæmia being 21 8% in both 980 treated and 999 controls

Within recent years it has come to be recognised that a diagnosis of toxæmia cannot be based on hypertension by itself, for this often connotes not a true or specific pregnancy toxæmia but an essential hypertension The exclusion from the above groups of women with hypertension as the sole clinical abnormality leaves those in whom the diagnosis of toxæmia is based on albuminuria, œdema, &c , with or without, but generally with, hypertension This treatment of the figures may exclude some cases in which the hypertension is due to toxæmia but any such disadvantage is offset by the fact that, apart from any possible differential benefit derived from the supplementary diet in one group, each group is being similarly treated It has the advantage of segregating for special study those cases in which the diagnosis of toxæmia rests on a reasonably secure foundation On this basis the primigravidæ who received the additional dietary ingredients had an incidence of toxæmia of 5 4%, while in the primigravidæ who did not receive any additional diet the percentage was 7 4 The difference and its standard error was 2 0 ± 0 9, which means that the odds are nearly 40 to 1 against such a result being obtained by mere chance The figures were also favourable to the parous women receiving the supplements but not to a significant degree, the percentages being 3 6 for treated and 5 2 for controls, and the difference 1 6 ± 0 9 (see table) The women receiving the special diet are therefore protected against the risk of toxæmia in a ratio which is almost 30% When it is remembered that, next to puerperal sepsis, toxæmia constitutes the most important cause of the maternal death-rate (about a fifth of the total), in addition to being one of the most fertile sources of chronic ill health after childbirth, the findings become highly significant This investigation has been carried out in the London area, in which the incidence of toxæmia is low, and a reduction of 1 8% has been obtained If a similar reduction could be obtained for the whole country it is estimated, on the basis of the annual number of births (approximately 600,000 in the immediate prewar years in England and Wales), that there would be 10,000 fewer cases of toxæmia in the year

—	No of women	Hypertension only		Albuminuria with or without hypertension		Hypertension with albuminuria, &c (“ pre-eclampsia ”)	
		No of cases	Percentage	No of cases	Percentage	No of cases	Percentage
Primips—							
Treated	1530	332	21 7	83	5 4	69	4 51
Controls	1512	368	24 3	112	7 4	97	6 42
Diff (C–T), and SE			2 6 ± 1 5		2 0 ± 0 9		1 91 ± 0 82
Multips—							
Treated	980	179	18 3	35	3 6	31	3 16
Controls	999	166	16 6	52	5 2	46	4 60
Diff (C–T), and SE			1 7 ± 1 7		1 6 ± 0 9		1 44 ± 0 87
Total	5021	1045		282		243	

SE = standard error

In a further classification based on the criteria generally accepted for “ pre-eclampsia ”—namely, hypertension with albuminuria, œdema, &c —the following toxæmia-rates were obtained treated primigravidæ 4 51%, untreated primigravidæ 6 42%, difference 1 91 ± 0 82 , treated multiparæ 3 16%, untreated multiparæ 4 60%, difference 1 44 ± 0 87 (see table)

THE INFANT

Prematurity —The committee found evidence, which it regards as statistically significant, of benefit to the infant from the improved diet of the pregnant mother The chances of a woman carrying her child to term are improved by the diet Thus, out of 1529 primigravidæ receiving additional diet, in 308 or 20 1 ± 1 10% the pregnancy ended prematurely (before the 40th week), while in 1512 primigravidæ who did not receive any addition prematurity occurred in 361 or 23 9 ± 1 10% The figures for multiparæ were almost the same—20 1 ± 1 33% for treated and 24 2 ± 1 33% for untreated The differences in both instances are greater than mere chance fluctuations The relatively greater proportion of deliveries at term among the treated women is of particular importance in view of the Registrar-General's finding that 50% of infantile deaths under one month are due to prematurity

Birth-weight of baby —For primigravidæ of all ages the difference is slight—7 18 ± 0 03 lb for the treated as against 7 17 ± 0 03 lb for the controls, but a similar comparison for age 30 and over reveals a wider range, the babies of treated mothers weighing 7 17 ± 0 7 lb as compared with 6 99 ± 0 07 lb in the controls The difference here is 0 18 lb , which approaches significance In the multiparæ of all ages the difference between the birth weight is 0 07 ± 0 05 lb , which is not significant, but the trend of the values favours the treated women, for in 3 out of the 4 age-groups their babies were slightly heavier There is a considerable difference in the average birth-weights in different hospitals In hospital B the mean value was 6 98 lb for babies of primigravidæ, against 7 22 lb and 7 42 lb in hospitals G and J The corresponding weights in the multiparæ class were 7 43 lb , 7 82 lb , and 7 89 lb The differences between these mean weights are statistically significant and the deviations merit further investigation

OTHER EFFECTS

The committee could not find any evidence that the vitamin and mineral additions to the dietary appreciably affected the risk of fever and sepsis after childbirth Nor did they find any appreciable influence on the character and duration of labour

An additional investigation under a special subcommittee with Sir Norman Bennett as chairman was arranged to study the effect of the special dietary on the teeth of the mothers It was possible to carry out the investigation in only 314 cases, at the East End Maternity Hospital, Hammersmith Hospital, the Royal Free Hospital (Eastman Clinic), St Thomas's Hospital and Queen Mary's Maternity Home The results were inconclusive One of the objects of the research was to see the effect on the teeth of the babies born of those mothers who had received the supplementary maternity diet, and it was planned to do this by means of a "follow-up" process of the children for five years, but owing to the war this was impossible

COMMENT

The committee emphasise that the investigation could not be expected to discover the full extent of the benefits of a well-balanced diet in the antenatal period They had to avoid the risk that vitamins and minerals intended for the mother would be merely added to the general family stock, the substances were therefore given in tablet or capsule form Moreover, as was to be expected, some women defaulted It may further be urged that the full value of such protective substances can be realised only when they are given in the form of natural foods For these reasons the committee feel that the results of the investigation, valuable as they are, should be regarded as pointing to the minimal rather than the maximal advantages of a well-balanced maternal dietary It should also be mentioned that the results obtained concerned women whose basic diet was probably somewhat better than that of similarly constituted groups of women at the present time

This comprehensive and controlled investigation furnishes for the first time clear evidence on questions which have long been in dispute The demonstration of the influence of a well-regulated diet on the health of mothers and on the development and well-being of their infants is of national importance Further, the message is addressed to all sections of the community, for it is not solely among the poorer classes that defective nutrition is prevalent At the same time, since poverty and malnutrition march hand in hand and since the poorer classes are relatively the most fertile, it follows that the ravages of faulty maternal nourishment fall with tragic emphasis on the mothers in poor homes and their children

The committee are indebted to Miss Gladys Kitchener, secretary of the People's League of Health, and to the secretarial staff for their work in this research

Reviews of Books

Year Book of General Therapeutics, 1941

Editor O W BETHEA, M D, professor of clinical medicine, Tulane University School of Medicine Chicago Year Book Publishers, London H K Lewis Pp 520 16*s* 6*d*

THIS volume is one of the most useful of a useful series Its aim being to present a full and concise account of new work in the various fields of treatment the main problem has been one of selection In this the editor's task has been lightened by war-time diminution in the volume of research and the number of foreign medical journals A large part of the new matter—about a fifth of the book—naturally deals with the sulphonamides, as the editor remarks, a collection of articles on this subject alone would easily constitute a fair-sized library The summaries and comments he has chosen are of real value Sulphathiazole is described as the most important sulphonamide in use and the drug to be preferred in almost all situations where chemotherapy is required Little mention is made of sulphadiazine, the newest of the group, but comparable figures are given of therapeutic results and toxicity in large series of cases treated with the other preparations The section gives a good summary of the present sulphonamide position, despite only one small reference to the use of sulphaguanidine in bacillary dysentery—an important omission in view of the wide need for dysentery control in war-time The sections on vitamins are also useful, and the accounts of vitamin-B complex are particularly good Papers are included on the use of synthetic vitamin K in cases of jaundice, and hypothrombinæmia with hæmorrhage, and of vitamin E (tocopherols)—applications as yet of more interest to the research worker than the general practitioner Practical methods in blood transfusion, intravenous and spinal anæsthesia and the red cell sedimentation-rate are set out, and information of the bromsulphthalein and other tests of liver function The use of phenothiazine in treating threadworms is noted but no mention of the serious toxic effects was possible before the date of publication, no doubt next year's volume will remedy this Amphetamine, atropine methylnitrate ('Eumydrin'), sodium diphenylhydantoinate ('Epanutin'), vaccine treatment of undulant fever, shock treatment of mental diseases, the treatment of burns and an account of synthetic ductless gland preparations, particularly testosterone and stilbœstrol, give some indication of the wide range of subjects covered It is never easy to judge fully the results or value of newly advancing therapeutics, at least as much cautious assessment is needed as the editor has given to this important volume

Adolescent or Ankylosing Spondylitis

S GILBERT SCOTT, M R C S, F F R, D M R E, consulting radiologist to the London Hospital, and hon radiologist to the British Red Cross London Humphrey Milford, Oxford University Press Pp 132 15*s*

THE late Dr Gilbert Scott's short monograph deals with his experience of a crippling disease, usually regarded as rather rare, at the Charterhouse Rheumatism Clinic, however, he detected some 300 cases over 10 years, and he emphasised the importance of early diagnosis at a stage when wide-field X-ray therapy may arrest progress of the disease Orthopædists and physiotherapists should be familiar with this subject, if the claims for wide-field therapy are substantiated this monograph will have served a good purpose

Massage, Manipulation and Local Anæsthesia

JAMES CYRIAX, M D Camb, assistant medical officer, physiotherapeutic department, St Thomas's Hospital London Hamish Hamilton Medical Books Pp 302 12*s* 6*d*

IN this little book Dr James Cyriax describes the methods which he and his colleagues use to treat minor injuries and disease He surveys the principles and technique of massage, mobilisations and general anæsthesia, and gives a useful chapter on referred pain He makes considerable use of procaine anæsthesia, not only in the Steindler test for establishing the site of referred pain, but to confirm diagnosis, as a therapeutic measure (following Leriche's technique), and to distinguish between neurosis and malingering Detailed directions are given for examining structures—muscles, tendons, ligaments and capsules—which may be giving rise to pain Conditions are arranged according to regions, and the chapter on sciatica is specially clear and full He recommends orthodox treatment for most things, and describes it well, but it is a pity that he did not give more detail of the technique of procaine therapy which has shown such excellent results He advocates early aspiration for effusions into the knee-joint in which most surgeons will support him, but he is not likely to find general agreement with his view that massage should be given next day Nor with another statement that adductor sprains invariably occur at the femoral insertion, they are usually found at the pubic attachment of the muscle The chief value of the book is the emphasis it lays on accurate diagnosis of minor aches and pains generally labelled lumbago, backache or muscular rheumatism These lesions, he insists, can be diagnosed accurately and he tells how Once diagnosed, they can usually be readily cured, he holds, by the methods he advises

THE LANCET

LONDON SATURDAY, JULY 4, 1942

SOLDIER'S DOCTOR

A MOTHER has been heard to rejoice because her doctor son is still a civilian " So many of his friends are in the Army learning absolutely nothing " Others have noted the attitude among their medical colleagues of ' Keep out as long as possible, it's no good to me ' If this attitude is common to the nation it is grave, if it is special to our profession it is unworthy of it, though there are extenuating circumstances It is said that there is little clinical medicine to be done in the Services " I have been with a field unit for three months and have never had more than three hours of medical work in one day " This fallacy arises in part from our having learned our medicine on patients already suffering from or at least suspected of suffering from serious disease, in part from the influence of the leaders of our profession, who spend their lives treating such No clinical medicine ? What is the proper name for the task of keeping a thousand men fit ? Sometimes these are the close-knit family of a battalion, sometimes the scattered clan of a transport unit, sometimes an incoherent group of many details These provide a great variety of practice if they are to be kept well It is a new type of clinical medicine from what the MO learnt as a student and needs a complete mental switchback which is one reason why the MO must be young, for if the mind of youth cannot switch none can Thus the MO may learn the kind of medicine which includes the giving of advice to the healthy human being in every detail of his daily life, from when he wakes to when he wakes again And when the soldier first goes sick he does so for the complaints which in civil life would be attended to by his mother or his wife, or perhaps by the pharmacist at his shop This again is clinical medicine, but at a stage that even the GP does not see In the military hospital, too, there is a different emphasis Here are congregated many ailments which in civil life would have meant a man dropping in on his panel doctor on the way home from work, or at most staying home from work for a day or two No civilian hospital would spare a bed for these cases, but the MO will find it worth while and not always simple to nip such ailments in the bud, to restore poise and confidence, and to make a man fighting fit without delay.

How can it be said that a doctor learns nothing in the Forces—unless he has lost the power to learn ? Professional knowledge is not enough to make a first-class army doctor He must know how to prevent disease, how to maintain the morale of troops, how to evacuate and treat the wounded quickly For his own safety he must be expert in field craft and be able to use map and compass like a scout But on the professional issue where can he get a quicker grasp of the slighter forms of sickness which with the increasing emphasis on prevention must come to fill a larger and larger part in clinical medicine ? It is a serious criticism of medical education if it has taught us that the only things worth learning are further details about pathological lesions and therapeutics And there is another item on the balance sheet To see the world, to meet men outside his own profession and his own upbringing, with different trainings and other aims in life these are a form of education as valuable as years of hospital appointments Most doctors now passing out of middle age will agree that the experience they gained in the last war left them better doctors than they could have been without it

CHEMOTHERAPY OF INTESTINAL INFECTIONS

UNTIL a year ago the treatment with drugs of bacterial infections of the intestine had been a dismal failure Substances which in the test-tube were actively bactericidal to the coli-typhoid organisms failed in experimental feeding tests to have any effect on the intestinal flora of mice, and since it is impossible to reproduce in animals infections simulating the natural intestinal diseases of man, experimental work on the action of various sulphonamides on the intestinal pathogens in vivo had little practical value Although sulphapyridine and sulphathiazole were found on clinical trial to have some curative value in bacillary dysentery, these drugs have the disadvantage, as far as intestinal infections are concerned, of being readily absorbed from the bowel and perhaps of being renal irritants in dehydrated patients with oliguria The introduction by MARSHALL and his colleagues of a sulphonamide compound, which while chemotherapeutically active was poorly absorbed, therefore heralded a real advance in intestinal antisepsis This drug, sulphaguanidine, has now been used in most of the intestinal infections; the results so far obtained were reviewed by Dr ROBERT CRUICKSHANK in opening a discussion on the subject at the RSM on June 9 The field is a wide one If typhoid fever is a disappearing disease, it is being replaced by the milder paratyphoid, Sonne dysentery is now a prevalent endemic infection in this country and outbreaks of Flexner dysentery are still too common in institutions Gastro-enteritis with hospital fatality-rates of 30–50% exacts a high toll of infant life, and that obscure and intractable disease, ulcerative colitis, still causes misery to many a man and woman

The treatment of typhoid and dysentery should have as its objectives bacteriological as well as clinical cure for the convalescent carrier state is common in both infections and may persist for weeks after clinical cure with detriment to the community Therefore in assessing the value of sulphaguanidine in these infections a bacteriological control using modern selective media should form part of the investigation On this basis the drug has failed completely in typhoid and paratyphoid fever HALL[1] in New Orleans treated 20 cases of typhoid with 20 controls, and found no significant difference in clinical course, complication-rate and duration of infectivity in the two series, two " intractable ' carriers were left in the treated group Dr PAUL BEESON[2] treated a series of 40 cases of paratyphoid with 48 controls in the recent Liverpool outbreak again, there was no response, clinically or bacteriologically, to the drug In dysentery, on the other hand, the results have been excellent Following the preliminary report of **Marshall** and his colleagues, **Anderson** and **Cruickshank**[3] treated 41 cases of Flexner dysentery with 55 controls in a LCC mental hospital, and despite small dosage reported good results both clinically and bacteriologically They found that not more than a quarter to half of the drug was excreted in the urine, and toxic effects were, with the exception of one rash, absent Their findings have been corroborated in the treatment of another series at the LCC North-Western Hospital It is particularly noteworthy that of 34 treated patients whose fæces were bacteriologically examined on desoxycholate citrate agar twice weekly only one gave positive cultures after the course of sulphaguanidine and he was probably reinfected, whereas 12 out of 31 untreated cases continued to excrete the Flexner organism for 10–40 days after onset Six of these untreated cases and two persistently positive symptomless carriers became bacteriologically negative within a few days of beginning a late course of sulphaguanidine In America, **Hardy** and his colleagues[4] have reported excellent results from the use of the drug in both clinical cases and carriers infected with Flexner organisms, so that the eradication of this infection from mental hospitals and other institutions is now a practical possibility

---

[1] Hall W M *Med surg J* 1941, 94 283

[2] See Holt H D Vaughan, A C T and Wright, H D *Lancet,* 1942, i, 133

The Army Medical Directorate[5] in its latest bulletin is enthusiastic about the drug in the treatment of severe Shiga dysentery With massive doses the outstanding clinical effects were a feeling of well-being within 24–48 hours with relief of abdominal pain and tenesmus, reduction of temperature and pulse-rate to normal in 1–3 days, reduction in the number of stools to normal in 5–6 days, and the rapid disappearance of blood, although mucus may persist for some time All workers agree that the earlier treatment is begun the better the clinical response and the more rapid the convalescence Doses of 50,000–100,000 units of concentrated Shiga antitoxin should be given intravenously to fulminating toxic cases of Shiga dysentery In the usually mild Sonne infections, where diarrhœa may last only for a day or two, chemotherapy is mainly directed to a bacteriological cure of the convalescent carrier and the results have not been particularly good For example, at the North-Western Hospital 4 out of 24 treated cases remained positive after the tenth day compared with 6 out of 18 untreated cases The dosage used in these and in the Flexner infections was 3 g thrice daily for 3 days followed by 3 g twice daily for 4 days in adults and half that dosage in children **Marshall** recommended an initial dose of 0 1 g per kg of body-weight and maintenance doses of 0 05 g per kg four-hourly until the diarrhœa was controlled when the same dose was given eight hourly for another few days In the Army, 20 g per day is given for severe infections, with a total dosage of 135 g While these massive doses may be required for severely ill patients, and might be tried to effect cure of the convalescent Sonne carrier, there is no doubt that the smaller doses control the less severe Flexner infections It is probably important in dysentery to give large doses infrequently in order to attain the maximum concentration of the drug at the seat of infection in the large bowel. Adequate fluids must be given to maintain a good renal flow.

There have been few reports on the use of the sulphonamides in the non-specific gastro enteritis of infants **Cooper**, **Zucker** and **Wagoner**[6] had no success from the use of sulphathiazole in gastroenteritis, and a limited experience with sulphaguanidine in this infection and in bacterial food-poisoning has been disappointing More benefit may come from the use of yet another new sulphonamide, succinyl sulphathiazole (or sulphasuxidine) which has in a proportion of cases entirely eliminated *Bacterium coli* from the intestinal tract The treatment of ulcerative colitis with sulphaguanidine by mouth has given variable results In **Cruickshank**'s experience a few moderately ill patients showed complete remission of symptoms but severe infections were unaffected **Bargen** and **Dearing**[7] reported clinical cure or improvement in 32 out of 46 cases, many of whom had been given other therapies Sir **Philip Manson-Bahr**, at the RSM discussion, advocated the use of retention enemata containing 7–10 g of the drug in 7 oz of water or mucilage, with morphine or phenobarbitone as a bowel-sedative In the treatment of amœbic dysentery, which masquerades under a variety of diagnoses, he pointed out that emetine, while an excellent drug for controlling an acute infection or metastatic complications, was ineffective against the amœbic cysts and therefore did not often effect complete cure To do so, he relied on 2-grain doses of emetine bismuth iodide given at night in hard gelatin capsules for 8–10 days combined with chiniofon (better known as 'Quinoxyl' or 'Yatren') given as a 2½% solution rectally Mention was also made of infection with *Giardia intestinalis*, which from its pullulation in the duodenum and possibly in the bile-ducts may initiate a subacute catarrhal enteritis, and for which mepacrine hydrochloride is apparently a specific remedy

FIRM BASIS FOR CHALK IN BREAD

In his work on rickets with dogs, **Mellanby** has long maintained that cereals contain a powerful rachitogenic agent which, in his paper with **Harrison**,[8] he concluded to be phytic acid It was not certain how far this conclusion applied to human beings, and no practical application of it has been recommended until recently In 1940 **McCance** and **Widdowson** completed an experiment with a simplified war-time dietary containing much flour of 92% extraction They have elaborated a model technique for long-term metabolic studies on human subjects, by which they and a group of their colleagues live, if necessary for months, on the experimental diet In this particular experiment the subjects maintained good health and working capacity, but when the results were analysed there was a suspicion that they had not been in positive calcium balance The doubt was a grave one and had to be settled The task of settling it was arduous but **McCance** and **Widdowson**, with their volunteers, tackled it[9] The chief question they set themselves to answer was

Do men and women absorb calcium less freely rom brown than from white bread dietaries ? " And if so, " Is phytic acid the noxious agent ? " They posed a number of subsidiary questions bearing on the nation s housekeeping So well were the questions chosen and the experiments planned that a fine harvest of clear answers was reaped All the subjects absorbed less calcium on the brown-bread diet than on the white, all who were in positive calcium balance on the white bread were in negative balance on the brown, and all who were in negative balance on the white were in a balance still more negative on the brown The answer was unequivocal The effect was reproduced by substituting white bread with added sodium phytate for the bread from 92% extraction flour Both the main questions were thus answered in the affirmative, a serious position was revealed and it was clear that something ought to be done about it Nutritional experts were pressing on nutritional grounds for a greater consumption of high-extraction flour At any time the blockade might make a change to a flour of higher extraction a necessity All the arguments were for lengthening the extraction save this one—that there was a risk to health by putting the population into negative calcium balance

Further experiments showed that there was a cheap and easy remedy by adding chalk to bread the situation could be saved The explanation of the whole matter seemed to be that the amount of phytic acid in flour increases with the degree of extraction, and that its effect is to precipitate the calcium, and incidentally some other salts, not only in the flour but also in the rest of the diet The magnitude of the danger depended on the relative amounts of phytic acid and calcium in the whole diet With a diet rich in milk and cheese, much brown bread, oatmeal and other cereals rich in phytic acid can be eaten with impunity, but unfortunately diets rich in milk and cheese are generally those which are low in bread, and those rich in bread are usually low in dairy products Correction could obviously not be made, at any rate in war-time, through any regulation of the supply of ordinary foodstuffs The remedy must be by addition of some cheap salt of calcium, not unpalatable, easily miscible and easily obtainable in the requisite quantities The carbonate and the monohydrogen phosphate were tested on the experimental subjects, the phosphate had no metabolic advantage and made a slightly less palatable bread The carbonate was cheaper and more plentiful, so the verdict was in its favour

The amount of chalk which should be added to a sack of flour depends on a number of considerations, of which the first is the extraction of the flour Having decided how much calcium is needed to " make safe " the given type of flour, we are next met by the question, " Shall we take advantage of the opportunity to add more than that calculated amount of calcium in order to neutralise any other phytic acid in the diet, and in addition bring up the calcium content of the whole diet to a level at which the human requirement of calcium, whatever we may have calculated that to be, is fully covered ? " This is a controversial question of great importance and McCance and Widdowson do little more than indicate its existence They do, however, stress the rather new concept that the quality and quantity of the cereal component of a diet should be taken into consideration in assessing the adequacy of its calcium content The recommendation they make is that calcium should be added to flour in an amount just sufficient to neutralise its phytic-acid content To achieve this purpose the amount of calcium, as calcium carbonate, to be added to every 100 g of flour should be for 69% extraction white flour 65 mg, for 85% extraction National flour 120 mg, and for 92% extraction " wholemeal " flour 200 mg The added calcium thus consumed in 1 lb of " wholemeal " bread would be rather less than that in a pint of milk The decision which the Ministry of Food has taken is to add enough calcium to National flour to reduce its calcium-immobilising activity to that of white flour, and, though there are dissentients, some of whom feel strongly about it, the majority of nutritionists will agree with Bacharach[10] in supporting this measure until a rise in our consumption of milk and other dairy produce can render it unnecessary

WITH THE EIGHTH ARMY

As the battle swung to and fro in Libya the medical services learnt new ways of meeting the needs of the wounded Last week (*Lancet*, June 27, p 766) we quoted the views of Colonel Julian Smith, acquired during the 1940 campaign Notes compiled from the reports of the consulting surgeon and the consulting orthopædic surgeon with the Middle East Forces between October and December, 1941, tell us something of the experience gained in another year's fighting[11] During the Eighth Army offensive which began last November the enormous area to be covered made it impossible for the surgeons to keep in continuous touch with the base, news—and examples—of their handiwork filtered back with casualties Ambulance cars had to be " navigated " across the desert, even for distances as short as 30 miles As soon as the base hospitals received a convoy the divisional surgeons were asked to report on the condition of patients on arrival, and their comments were passed on to Army medical officers None of the surgeons in the battle zone became casualties though they worked under fire and sometimes even as captives The enemy, it seems, respects the Red Cross " so long as it does not conflict with his interpretation of the needs of the tactical situation " Apart from the enemy and his interpretations, surgeons were hampered by delay in communications, by the priority demands of the fighting forces for transport, by shortage of water, and by lighting problems in the operating tents The delays were mainly between administrative headquarters and units, or between sections of units When touch was lost cases would collect and flood a centre for hours before help could reach them Shortage of water had been foreseen but was none the less awkward when it came to sterilising instruments and washing towels It was necessary at times to operate by the light of hurricane lamps or signal flash-lamps with a lead to the lorry battery Records are frankly described as bad—" surgeons will not write legibly and print their names " This, a harmless foible in peace-time, can mean trouble for a patient who arrives at the base without a legible line to say what has been done beneath the plaster or what doses of sulphonamide he has received More messages could have been written on the plasters themselves, it was felt, a plan ensuring culous—can produce a phlycten The evidence for these conclusions comes from an elaborate research at the White Oak Hospital, Swanley, extending over the six years 1935–40, in which radiological evidence of tuberculosis was found in 72% of phlycten cases, against 12% of controls (blepharitis patients admitted to the same hospital) The interpretation of doubtful radiograms of the chest must be subject to the personal factor, and certainly few observers have found anything approaching this high figure, but much other evidence is forthcoming, and as sifted and presented by Sorsby it does seem to show that tuberculous infection can act as the sensitising agent of phlyctenular ophthalmia If so, sufferers from phlyctens must be regarded as in a dangerous state of health and needing antituberculous treatment

USE AND ABUSE OF THE ELECTROCARDIOGRAM

OUR American colleagues are concerned about the uses to which the electrocardiogram is being put, and the American Heart Association has received requests from responsible cardiologists asking for measures to ensure that practitioners can find out whether a consultant is competent to interpret electrocardiograms Over here the problem has never been so serious, but there is a tendency for too much to be read into electrocardiograms Workers at Yale,[1] in an attempt to assess the clinical value of electrocardiography, and the significance of its increased use, have analysed the electrocardiograms taken at their hospital during the last 12 years They found that, while the mortality from heart disease has risen rather less than 20%, the number of electrocardiograms taken per 100 medical patients has more than doubled (15 5–38 9%) During this period the percentage of abnormal electrocardiograms increased from 58 9 to 66 6, suggesting that electrocardiography was not being wasted on patients without heart disease They compared a fair selection of electrocardiograms from a year when relatively few were taken with a similar selection from a later year in which twice as many were taken , they found that in the later year the percentage of insignificant records was smaller, and the percentage of clinically helpful records higher, than in the earlier year They also recorded electrocardiograms in 400 patients for whom electrocardiography was not requested by the physician in charge , 78% of these showed abnormalities which were wholly unexpected after careful clinical examination They naturally conclude that the increasing use of electrocardiography is justified by the results, though they admit that it is not desirable as a routine It should be noted, however, that their results are based on the findings in a large well-run hospital, where selection of cases can be made without reference to expense The problem is entirely different in general practice or in smaller hospitals Again, we encounter the old problem of the significance of slight deviations in the electrocardiogram, some of which the Yale workers accept as abnormalities Have we sufficient evidence at present that these really are abnormal ? It is here that mistakes are most commonly made, as Marvin[2] points out Such findings as low voltage curves, isolated changes in Q or T waves or the QRS complex are of no clinical significance by themselves, though in conjunction with clinical and radiological findings they may be , but to attempt to give a clinical interpretation of such an electrocardiogram without relation to the clinical evidence in the case is rash The indications for electrocardiography are wide and definite in the recognition of the arrhythmias it stands supreme , in diseases such as acute rheumatism and diphtheria where we know the heart to be affected it often provides evidence of myocardial damage which might be otherwise missed , the diagnosis of myocardial infarction often depends on serial electrocardiography, and it can be used to an disorders of conduction, though the diagnosis of bundle branch block is still too often made on insuffi grounds Moreover the scope of clinical electrocardiography is ever widening But this invaluable adjunct diagnosis, treatment and prognosis may be discr if it is delivered over to the enthusiasms of those not fully trained in its use

CLEAN HANDS

THE importance of the intact skin as a protection against the entry into the body of pathogenic organisms is well appreciated by those who handle infected wounds and similar lesions Not only does the skin present a mechanical barrier to the entry of organisms but it has the power to remove bacteria that are deliberately placed on it Colebrook[1] showed that pathogenic streptococci rapidly disappear from the hands, and that they are not killed by the simple process of drying but are apparently destroyed in some way by the skin Recently Burtenshaw[2] has tried to find an explanation of this phenomenon by making extracts of the skin and its appendages He found that they contained certain long chain fatty acids and soaps which he showed could kill streptococci in vitro While this may explain the disappearance of streptococci it does not explain the rapid removal from normal skin of a variety of other organisms, including gram-negative ones that are insensitive to soaps and fatty acids Arnold,[3] who has worked with such organisms, found that the self-disinfecting power of the skin was enhanced if the cornified layer was cleaned and freed from fat He believed that the relative acidity of normal skin might be responsible for destroying organisms placed on it Marchionini,[4] who has studied the reaction of the skin, has found its acidity to be highest in the exposed parts and lowest in the axillæ, groins, &c , where he believed the production of sweat prevents the concentration of acid from rising Arnold found that the skin of a dog that had been recently shaved had lost its power to remove organisms, and at the same time its acidity disappeared This was possibly related to microscopic damage to the cornified layers, and the skin returned to normal within 24 hours It is doubtful however whether the highest degrees of acidity recorded for the skin are enough to destroy many of the bacteria that are known to disappear from its surface These points might be further investigated, for they are of some practical importance Were the skin to lose its self-disinfecting powers surgeons and nurses might rapidly become the carriers of a variety of pathogenic bacteria Indeed, it is now recognised that a certain number do carry pathogenic strains of staphylococci The normal skin has apparently no power to remove staphylococci It is important to know how the skin should be treated in order to enhance this valuable property Excessive cleaning may remove bactericidal substances from the skin, or by keeping the corneal layers clean may allow them to act more efficiently The frequent use of the scrubbing brush may do more harm than good by damaging temporarily, at any rate, the corneal layer Another interesting point is whether the epithelium over scar tissue has the same power of removing bacteria as has normal skin Extensive scars, such as follow burns are notoriously liable to become the seat of repeated minor infections This is possibly due, in part at any rate, to the impairment of its nutrition by the contraction of the fibrous tissue beneath, or the properties of the skin itself may play a part Since this skin is devoid of the usual appendages, hair follicles and sweat glands, investigations might be able to demonstrate whether or not these structures help in removing bacteria from skin

In England Now

A Running Commentary by Peripatetic Correspondents

MANY of us, I fancy, will deplore the curtailing of the medical curriculum even as an emergency measure. This may in part be mere envy because no such privilege was accorded to us of a previous generation of medical students, but I suspect that it goes deeper than that. GP's will recall how ignorant they were when first qualified and how slowly and laboriously knowledge of the treatment and above all of the management of sick persons (and their relatives) had to be acquired. The best books on medicine are the patients themselves and 36 months is little enough in all conscience to give to clinical work, even then it has to be packed in with a great deal of extra clinical activity. If some abridgment was necessary it would, I think, have been infinitely wiser to have made it during the preclinical stage. The detailed study of anatomy, for example, is at best a mere feat of memory and at worst a stultifying experience. Most of it is soon forgotten and quite useless in general practice and I have heard even surgeons admit that its importance is grossly exaggerated.

* * *

Not long ago I had the ill luck to be sent for a short period of rest, so called, to a hospital in the throes of a quiet spell. All the casualties of the last blitz were by then discharged or required only occasional attention. The garrison troops in the area were temporarily withdrawn and things had come to a virtual standstill. As a result I was for the first time reduced to studying the art of killing time. By rising late and prolonging one's elevenses the semblance of working in the morning could be maintained. In the afternoon, when the chronic inclemency of the weather permitted it, the custom was to walk to the village about four miles away; on wet afternoons one read or slept according to inclination. During those dreadful hours between tea and dinner a spirit of restlessness seemed to possess everybody. To add to this uncertainty the afternoon mail might fail to arrive if the office boy was too busy drawing aeroplanes to sort it. If the musician of the staff received no letters he became of all men the most miserable and proceeded to hammer out the most melancholy of Chopin's preludes on the sitting-room piano in the hope that he would succeed in making others as depressed as he was. Like all true artists he was impervious alike to criticism and witticism but he knows now that it is hopeless to try to compete with the wireless turned full on. I even managed to convince him that the set was capable of switching itself on without human aid.

In the evening after the best meal of the day and in front of a comfortable fire feelings mellowed and even the musician became good enough company, provided he would leave his wretched piano alone. This part of the day was customarily employed by the staff in games of skill and chance—bridge, draughts and (tell it not in Gath) vingt-et-un. I never cared much for gambling and consequently was the proper prey of the chess enthusiast of the company. He would have made a pleasant opponent if he could have dissociated business and pleasure, but he was a pathologist and insisted on an exhaustive post-mortem analysis of every game. The more severely he was beaten the longer was the autopsy, and since I usually emerged victorious I soon found it unbearable. I once asked the junior physician where the billiard-table was, only to be told that neither he nor his colleagues had had time to loaf around the Union in their undergraduate days. After that rebuff I dared not unpack the dart-board I had brought with me. They would never have believed that I acquired proficiency in the game while on a voyage for my health.

For some reason table-tennis was considered eminently respectable and was played in season and out by all and sundry. When the medical superintendent played against the surgeon we all pretended to an appreciative interest in the decorous but herculean struggle between two master minds, but when the residents began to play there was an immediate exit of all the other occupants of the room. I used to think that this rush for safety was uncourteous if not undignified on the part of the permanent staff until one day I surprised the mess secretary in some abstruse calculations which involved the use of a slide-rule. He told me he was working out the bonuses due to his colleagues for prowess at ping-pong, it appeared that some system of extra points was allowed on the following basis. For doing violence to the person or property of anyone in the room, 2 points. For a bull's eye registered on the bald spot on the back of the surgeon's head, 5 points. For upsetting the pathologist's chess board 10 points. For knocking off the physician's pince-nez 20 points. As the residents played with abandon it is small wonder that their seniors considered discretion the better part of valour and retired on the commencement of hostilities.

I don't expect there is much time for recreation in that hospital now, for they received a train-load of casualties after the last blitz in the neighbourhood. I enjoyed my stay there and am grateful to those people for beginning a hitherto neglected side of my education.

* * *

We badly need a proverb to sum up the fact that the obvious, unless it has actually been thought about, can still surprise us. "You never miss the water till the well runs dry" is about as near as we get, but this reflects only one aspect of the whole. Recently I have seen something of veterinary surgeons at work, and here many of the surprises were really quite obvious implications of the differences between their patients and ours. For example, if one had thought about the doses of sulphonamides needed for cattle, obviously one would have expected them to be large. But I had never given it a thought and consequently the sight of 7 lb drums of the drugs on the shelves astonished me no less than the instructions to "Give him two ounces right away." Similarly with midwifery, remembering the manual strength that is often required did not prepare me for the sight of ropes and pulleys, and the request that all the available man-power should heave hard. One object that baffled me completely was a long tube of very hard leather about the thickness of the handle of a tennis racket. This turned out to be a stomach-tube, and later I saw it used with something like the result that I imagine would follow a direct hit on a barrage balloon. These qualitative differences, however, were small compared with one difference in kind which filled me with apprehension at the thought that it might ever be applied in human medicine. An aspect of treatment that I had never considered is the relative value of the animal and the treatment. Nobody is going to give treatment worth £5 to an animal worth £1; but how awful a thought that one might have to decide whether or not Mr A's usefulness to the community justified removal of his appendix.

* * *

It is high time that someone called the bluff on the present craze for extolling the young. The whole suggestion seems to be that if only "the young" were in control how different everything would be. Who are included in this exclusive group? Physiologically we start growing old from the moment we are conceived. We are probably at our physical prime in the early twenties. When are we at our mental prime? I was brought up by a chief who never tired of pointing out that a man's best work was done before he was 30. At the time (in my early twenties) I found this rather depressing, but I have no doubt now that, like many of his opinions, there is a great deal of truth in it, especially in the modified form that unless a man has shown promise and produced some good work before he is 30 he is not likely to be outstanding. This of course applies particularly to research. In other spheres the story may be different. Some men, for instance, mature late but nevertheless turn out better than the scintillating young man of the early twenties who is unable to maintain the pace. The real clinician may be born and not bred but for most of us clinical acumen is the result of long and often bitter experience, and the same applies to the statesman.

The young may have more generous impulses, be less bound by conventions and have more imagination, but they have not the experience of life which is essential in handling men and women. When short sharp bursts of energy and initiative are required they are undoubtedly supreme, but in long-sustained efforts such as leading a community they can only supply some of the energy, the actual leadership requires other attributes which only come with experience. One only needs to study culous—can produce a phlycten. The evidence for these conclusions comes from an elaborate research at the White Oak Hospital, Swanley, extending over the six years 1935–40, in which radiological evidence of tuberculosis was found in 72% of phlycten cases, against 12% of controls (blepharitis patients admitted to the same hospital). The interpretation of doubtful radiograms of the chest must be subject to the personal factor, and certainly few observers have found anything approaching this high figure, but much other evidence is forthcoming, and as sifted and presented by Sorsby it does seem to show that tuberculous infection can act as the sensitising agent of phlyctenular ophthalmia. If so, sufferers from phlyctens must be regarded as in a dangerous state of health and needing antituberculous treatment.

USE AND ABUSE OF THE ELECTROCARDIOGRAM

OUR American colleagues are concerned about the uses to which the electrocardiogram is being put, and the American Heart Association has received requests from responsible cardiologists asking for measures to ensure that practitioners can find out whether a consultant is competent to interpret electrocardiograms. Over here the problem has never been so serious, but there is a tendency for too much to be read into electrocardiograms. Workers at Yale,[1] in an attempt to assess the clinical value of electrocardiography, and the significance of its increased use, have analysed the electrocardiograms taken at their hospital during the last 12 years. They found that, while the mortality from heart disease has risen rather less than 20%, the number of electrocardiograms taken per 100 medical patients has more than doubled (15.5–38.9%). During this period the percentage of abnormal electrocardiograms increased from 58.9 to 66.6, suggesting that electrocardiography was not being wasted on patients without heart disease. They compared a fair selection of electrocardiograms from a year when relatively few were taken with a similar selection from a later year in which twice as many were taken; they found that in the later year the percentage of insignificant records was smaller, and the percentage of clinically helpful records higher, than in the earlier year. They also recorded electrocardiograms in 400 patients for whom electrocardiography was not requested by the physician in charge; 78% of these showed abnormalities which were wholly unexpected after careful clinical examination. They naturally conclude that the increasing use of electrocardiography is justified by the results, though they admit that it is not desirable as a routine. It should be noted, however, that their results are based on the findings in a large well run hospital, where selection of cases can be made without reference to expense. The problem is entirely different in general practice or in smaller hospitals. Again, we encounter the old problem of the significance of slight deviations in the electrocardiogram, some of which the Yale workers accept as abnormalities. Have we sufficient evidence at present that these really are abnormal? It is here that mistakes are most commonly made, as Marvin[2] points out. Such findings as low voltage curves, isolated changes in Q or T waves or the QRS complex are of no clinical significance by themselves, though in conjunction with clinical and radiological findings they may be; but to attempt to give a clinical interpretation of such an electrocardiogram without relation to the clinical evidence in the case is rash. The indications for electrocardiography are wide and definite: in the recognition of the arrhythmias it stands supreme; in diseases such as acute rheumatism and diphtheria where we know the heart to be affected it often provides evidence of myocardial damage which might be otherwise missed; the diagnosis of myocardial infarction often depends on serial electrocardiography, and it can be used to a disorders of conduction, though the diagnosis of b branch block is still too often made on insuffi grounds. Moreover the scope of clinical electrocardiography is ever widening. But this invaluable adjunct diagnosis, treatment and prognosis may be discredited if it is delivered over to the enthusiasms of those not fully trained in its use.

CLEAN HANDS

THE importance of the intact skin as a protection against the entry into the body of pathogenic organisms is well appreciated by those who handle infected wounds and similar lesions. Not only does the skin present a mechanical barrier to the entry of organisms but it has the power to remove bacteria that are deliberately placed on it. Colebrook[1] showed that pathogenic streptococci rapidly disappear from the hands, and that they are not killed by the simple process of drying but are apparently destroyed in some way by the skin. Recently Burtenshaw[2] has tried to find an explanation of this phenomenon by making extracts of the skin and its appendages. He found that they contained certain long chain fatty acids and soaps which he showed could kill streptococci in vitro. While this may explain the disappearance of streptococci it does not explain the rapid removal from normal skin of a variety of other organisms, including gram-negative ones that are insensitive to soaps and fatty acids. Arnold,[3] who has worked with such organisms, found that the self-disinfecting power of the skin was enhanced if the cornified layer was cleaned and freed from fat. He believed that the relative acidity of normal skin might be responsible for destroying organisms placed on it. Marchionini,[4] who has studied the reaction of the skin, has found its acidity to be highest in the exposed parts and lowest in the axillæ, groins, &c., where he believed the production of sweat prevents the concentration of acid from rising. Arnold found that the skin of a dog that had been recently shaved had lost its power to remove organisms, and at the same time its acidity disappeared. This was possibly related to microscopic damage to the cornified layers, and the skin returned to normal within 24 hours. It is doubtful however whether the highest degrees of acidity recorded for the skin are enough to destroy many of the bacteria that are known to disappear from its surface. These points might be further investigated, for they are of some practical importance. Were the skin to lose its self disinfecting powers, surgeons and nurses might rapidly become the carriers of a variety of pathogenic bacteria. Indeed, it is now recognised that a certain number do carry pathogenic strains of staphylococci. The normal skin has apparently no power to remove staphylococci. It is important to know how the skin should be treated in order to enhance this valuable property. Excessive cleaning may remove bactericidal substances from the skin, or by keeping the corneal layers clean may allow them to act more efficiently. The frequent use of the scrubbing brush may do more harm than good by damaging temporarily, at any rate, the corneal layer. Another interesting point is whether the epithelium over scar tissue has the same power of removing bacteria as has normal skin. Extensive scars, such as follow burns, are notoriously liable to become the seat of repeated minor infections. This is possibly due, in part at any rate, to the impairment of its nutrition by the contraction of the fibrous tissue beneath, or the properties of the skin itself may play a part. Since this skin is devoid of the usual appendages, hair follicles and sweat glands, investigations might be able to demonstrate whether or not these structures help in removing bacteria from skin.

Nobody is going to give treatment worth £5 to an animal worth £1, but how awful a thought that one might have to decide whether or not Mr A's usefulness to the community justified removal of his appendix.

* * *

It is high time that someone called the bluff on the present craze for extolling the young. The whole suggestion seems to be that if only "the young" were in control how different everything would be. Who are included in this exclusive group? Physiologically we start growing old from the moment we are conceived. We are probably at our physical prime in the early twenties. When are we at our mental prime? I was brought up by a chief who never tired of pointing out that a man's best work was done before he was 30. At the time (in my early twenties) I found this rather depressing, but I have no doubt now that, like many of his opinions, there is a great deal of truth in it, especially in the modified form that unless a man has shown promise and produced some good work before he is 30 he is not likely to be outstanding. This of course applies particularly to research. In other spheres the story may be different. Some men, for instance, mature late but nevertheless turn out better than the scintillating young man of the early twenties who is unable to maintain the pace. The real clinician may be born and not bred but for most of us clinical acumen is the result of long and often bitter experience, and the same applies to the statesman.

The young may have more generous impulses, be less bound by conventions and have more imagination, but they have not the experience of life which is essential in handling men and women. When short sharp bursts of energy and initiative are required they are undoubtedly supreme, but in long-sustained efforts such as leading a community they can only supply some of the energy, the actual leadership requires other attributes which only come with experience. One only needs to study the painfully inadequate attempts which certain groups of medical students have made to produce memoranda on the subject of medical education Catch-words, the fashions of the moment—all these are incorporated And worst of all there is a nagging insistence on their own importance and a complete lack of appreciation of what their seniors have accomplished

Since the introduction of universal suffrage the citizen has been considered capable of recording a vote at 21 What difference has this tremendous influx of the young to the electoral roll made to the membership of the House of Commons? What percentage have ever troubled to record their votes? Or, to take an example nearer home, what part do the junior members of the honorary staffs play in running our teaching hospitals? How many of them are prepared to settle down to the task of producing a reasoned scheme which will prove practical? How many have been content to produce some novel idea and then collapse like a pricked balloon as soon as any criticism was offered? Modern youth is no better and no worse than preceding generations, but I wish someone would take them in hand, reintroduce a little discipline into our life and silence their querulous whimperings Let youth pull itself together, get down to a little hard thinking and chatter less Let them realise, and their elders as well, that we are all part of a whole The ripe experience of age in cooperation with the initiative and energy of youth will go far, but youth alone will only land us in unpredictable, instead of known, dangers The present position in Germany should be an ample warning of the purgatory in which misguided youth can land a nation

* * *

Coming over in the ship I met a captain of signals, whose hobby had become his job—pigeons He had a dozen with him and liberated them when six miles from shore They circled round for ten minutes before being lost to sight "Funny if they refused to leave you," I said "They do home back to their basket sometimes if they're flighted too often," he answered He said, and I put it in my "awaits confirmation" box, that pigeons never flight in the dark, they come down wherever they are He also said there were too many peregrines about

In the train I sat opposite a young man who had come down to see his sick father Pain over the heart and down the left arm, dyspnœa at night, sounded bad enough The doctor had warned him for anything, but wisely had not branded it with a name He himself was an asthmatic, but I think I might have deduced that from the shoulders and keen, anxious eyes In 50 miles he gave me a brief résume of all the treatments he'd had since boyhood The best one was living in London He was a designer and has turned over to precision instrument making and is on night-work He is very struck by the immutable methodicalness of the professionals, everything has to be in its exact place on the bench He said that their union meetings for which they had time off generally resolve themselves into personal wrangles between the elder men as to who had the most experience and so on His hobby is painting and he has literary aspirations We changed trains together and got into a darkening carriage with five sailors They had been torpedoed and were longing to tell us more about it, but didn't Expansion is so much commoner with the English than repression They'd switched off the light, so that they could have the curtain up and the window open—a touch of claustrophobia here Expansion and claustrophobia are, I suppose, mental states which protect the herd against the individual, repression and agoraphobia protect the individual against the herd, most of us keep an uneasy balance The carriage grew darker My first friend's head rested on my shoulder and I could feel his troubled breathing—his father's illness, his work to-night, his untidiness, his writing A sailor's leg touched mine, but changed position often, restlessly, almost angrily Mankind has lost nine-tenths of his tactile sensibility If I were a cat, I could probably tell what they are dreaming about My dog always sleeps with a bit of him touching me Children have a fair tactile sense When they are going to have a meal they think of it in terms of the taste and the feel of it in their mouths, when they're going to swim they feel the water round them hours before, they love nakedness, clothes can be a torture, hair-cutting purgatory What's that up on the rack? O, the Cheshire "Of course, my dear boy, I think entirely as smell, t and touch, at any rate for present use When I want do a little future thinking, I may throw a picture or but it's an effort Words, those obscene noises you how can you possibly think in those! Don't be a Snore—kick—rattle "That's why I enjoy the sun much, and being stroked and prolonged n propagation" He chuckled and faded Snort— "Gawd, what's that?" Dawn and Paddington

---

A NATIONAL MEDICAL SERVICE SCHE

THE National Health Association, which has headquarters in Tunbridge Wells, advocates the fo tion of a National Medical Service based on democ principles and under the control of the local governm administration and insurance committees

They have drawn up the following scheme A nati medical service should extend over the widest possi area, including, in particular, rural districts It sh be administrated by joint health advisory boards, which would advise units in their respective areas on the implementation of improvements in institutional, industrial and domiciliary services The boards would cover the areas as defined by local government The service would thus work as a compact unit for t preservation of health and the prevention of ill heal as well as to secure early diagnosis and provide the m modern facilities for medical treatment under cent advisory direction

Under the Local Government Act 1929, authorities empowered to unite and form joint boards, having adviso and executive powers These authorities include coun councils, county boroughs, and municipal, urban and ru authorities Machinery thus already exists for the establish ment of joint health advisory boards These would act in con junction with already established medical authorities. Complete coordination of institutional, industrial and domiciliary medical services should be assured by these boards without interfering with the executive powers of local government bodies

An efficient national medical service should be divided into institutional, industrial and domiciliary services Institutional services, in the main impersonal, can be administered with efficiency by local authorities under the existing Public Health Acts Institutional medical services, consisting of hospitals, clinics (diagnostic and treatment), rehabilitation centres, specialist services (accident, blind and deaf, orthopædic, dental, infectious diseases, maternity and child welfare, mental deficiency, ophthalmic, nursing, pathology), poor law services, school medical services, tuberculosis, and venereal disease services, and such others as may be found necessary or desirable They would in the main be administered by appropriate public health authorities, which would be responsible through the joint health advisory board to the Minister of Health

Industrial medical services are administered in factories in peace time by the Factory Department of the Home Office, but in war-time by the Minister of Labour and National Service, in mines by the Minister of Mines, on railways by the Minister of Transport, and in merchant shipping by the President of the Board of Trade Such division of authority is inconsistent with an efficient national medical service Local authorities are the most appropriate bodies to administer the scheme

Domiciliary services comprise medical and pharmaceutical services in collaboration with facilities for specialist diagnosis and treatment in clinics under the institutional service Free choice of medical attendant and free acceptance by a medical practitioner are matters of fundamental importance for a democratic medical service A capitation scheme of payment coupled with a basic salary for the medical practitioner is essential Domiciliary service should be administered through insurance committees in the respective district of each author ity, and these committees would be responsible through the joint health advisory board to the Minister of Health

Ninety-five per cent of the population is in receipt of incomes of under £500 a year, it is proposed that they and their dependants should be covered by insurance for medical benefit, but without prejudice to their right to be privately attended by a doctor of their own choice The cost of institutional, industrial and domiciliary services could be covered by contributory insurances with Exchequer grants in aid

Public Health

Venereal Diseases in War-time

AN increase in venereal diseases is expected in war-time obvious reasons and in the present war some nificant increase did occur in the first stage—between unich and the declaration. Since then, judging from e annual reports for 1940 and the preliminary figures 1941, there has been no further rise What was ared most was that the establishment of aerodromes in ral districts would lead to extensive syphilisation of the pulation outside the great towns, for the records of e VD clinics gave evidence that syphilis was not mmon outside great cities and ports and since the last ar had declined greatly In the last war a great crease in venereal disease, especially syphilis, was pected, but it turned out to be far smaller than the ssimists predicted or the optimists feared The enereal-diseases service came into existence in 1914 nd by 1918 was going strong, but since in this country e have no compulsory notification of syphilis and ttendance at clinics is voluntary, the clinic records do ot give us full information of the incidence of venereal iseases We cannot say of syphilis, as we can of berculosis, whether the disease is rising or falling and so to what extent In 1939 there was a brisk rise in ases of primary syphilis reported from the clinics, but his does not seem to have been maintained Many linics report an increase in new cases in 1940 over past ears, but others a decrease ; nearly all report a lowered ttendance which in the disturbance of the population is ot surprising

An interesting table showing the trend of fatal syphilis ince 1915 is given by Dr W M Fraser in his annual eport of Liverpool for 1940 In quinquennial periods, he numbers of deaths attributed to syphilis were 259, 55, 169, 189, 267, but when these deaths are analysed it ecomes apparent that the figures are stultified by teadily improved differential diagnosis of cardiovascular lesions Deaths attributed to congenital yphilis in the five five-yearly periods were 179, 188, 83, 33, 26 The great drop between the second and third periods may be due to more accurate diagnosis, for the Wassermann reaction was not often employed before 1925 , but the drop in the past fifteen years is probably an accurate expression of what is happening Deaths attributed to syphilis at ages 1–40 were 47, 35, 17, 30, 26 In the 25 years deaths from locomotor ataxy sank from 80 to 56 and those from general paresis from 272 to 105 Figures for incidence are not available, so the drop in fatalities may be due to decreased incidence, decreased virulence, or improved treatment Probably all these factors are involved Virulence of syphilis has been declining for fifty years or more, long before the treatment of the disease by arsenicals was introduced This modern treatment has almost abolished the secondary and tertiary syphilides, but it was feared at one time that it might favour the remote parasyphilides The figures from Liverpool, especially the well-marked reduction in fatal general paresis, suggest that this fear is without foundation

Substitutes and Adulterants

The brief typewritten report of Mr G H Walker, city analyst of Salford, deals mainly with war-time substitutes for foodstuffs Some of these substitutes, such as for onion, are purchased by the public mainly for flavouring and are unobjectionable if they have the flavours ascribed to them, provided they contain no deleterious substances and do not purport to supply anything but flavour Most of them, however, advertise a vitamin content which, as was pointed out in these columns on May 16 (p 593), is found deficient on analysis The public may be defrauded either advertently by the substance never having had the vitamin content claimed, or inadvertently by its having lost it since it was manufactured If the substance is advertised to contain so many units of vitamins it is an offence if at the time of purchase it contains less But if it is stated clearly that the substance contained so many units at the time of manufacture and that these may be reduced by keeping there is no offence Such labelling is not good advertisement and is often omitted Mr Walker mentions one egg substitute which was labelled "egg mixture" and "dried new laid eggs" It was found to consist of two-thirds dried egg and a third soya-bean meal This is a good article and would pass were it not for the misleading subtitle An accurate descriptive labelling would surely have been good trade advertisement, for an egg mixture guaranteed to contain two-thirds of its weight of dried eggs is better value than the public expects Two samples of curry powder were found to contain 40 and 85 parts per million of lead, which comes from rubbing turmeric root with chromate of lead to improve its colour This is an old offence, but the increased use of curry powder to give flavour and variety to war-time diet has brought it into importance An occasional curry containing this small quantity of lead might not matter much, but in households where a curry once or more a week has become customary the danger of chronic lead poisoning cannot be overlooked The practice of "improving" turmeric with chromate of lead should be stopped immediately Mr Walker draws attention to samples of milk deficient in solids other than fat which are proved not to be watered by the Hortvet freezing test The position of this test as legal evidence is not quite clear For the defence, proof that the sample passed this test would cause a prosecution for tampering to be dismissed in any court , but would proof that the sample did not pass the test, unsupported by other evidence, be sufficient to ensure a conviction ?

Child Health

The reports of the school medical officers for 1941, though shorn of much of their prewar embellishment, retain their importance The circular of the Minister of Health which demands the suppression of population information where it would be most interesting, does not apply to the school reports, which are governed by the Board of Education Circular of December, 1941 ; this urged brevity, but required " A statement of the general effect of the war on the physical and mental welfare of the children, with special reference . " to nearly everything in the province of school medicine ! That is a tall order, for apart from actual destruction caused by air-raids, the effect of war conditions on child life will not be revealed save by long and detailed observation Briefly no school medical officer reports any extensive or well-marked influence on nutrition, physical state or mental condition of the children due to war conditions, but most notice a deterioration of cleanliness and a rise in scabies Dr Christopher Rolleston (Rutland county), whose reports are always amusing and enlightening, says that the nutrition of the children in his district is better than ever and this cannot be accounted to extra milk or school dinners He says "In the boarding-schools of the nineteenth century the extremely sparse diets provided did but little harm, as 15 weeks were spent in the comfortable homes of the Victorian era" This raises the question whether full nutrition can be maintained on a diet alternately above and below requirement Dr Rolleston also calls attention to cases of suppurating scalps which he says yield to the newer remedies In the last war, persistent suppurations were frequent in children, by some attributed, with little reason, to the war bread of the period Possibly insufficiency of vitamin A played some part in producing the suppurating scalps and whitlows which were certainly unusually prevalent in 1917–20

Dr Miller Young of Glasgow, Dr H M Cohen of Sheffield, Dr James Mitchell of Birmingham, and Dr St Clair Stockwell of Leeds report slight deteriorations in the health and nutrition of the children from the standards of 1939 , but Dr John Yule of Stockport and Dr J A Fairer of Leicestershire found no alteration The school dentists generally call attention to increased prevalence of foul mouths and gum diseases Mr Drummond Kinnear of Leeds mentions specially severe gingivitis and Vincent's angina (trench mouth) Dr Mitchell of Birmingham says "some of our children are less well cared for than formerly" , he mentions a definite rise in incidence of impetigo and "rashes ascribed to unsuitability of food" and more postural deformities indicating lower muscular tone and increased fatigue The children are noisier and less controlled than formerly but there has been no appreciable rise in nervous diseases Dr Young found no definite signs of deterioration in major respects in the condition of Glasgow children, but he mentions an increase in suppurating ears, scabies and minor affections of the gums, nose, throat and lungs The trend of children to become taller and heavier, which set in after the last war, was maintained in 1941 Dr Cohen of Sheffield *also notes an increase in minor ailments of the throat and* respiratory system which " do not recover as quickly as might be expected," and in dry skin diseases " attributable to shortage of fat and lack of fresh fruit and vegetables " There appears to be no increase in neuroses anywhere and special war neuroses have been sought but not found

The impressions conveyed by reading the school reports which have come to hand are insufficient fats in the war-time dietary of children, and, in the cities, insufficiency of vegetables to take the place of fruits now unobtainable , doubtful insufficiency of first-class protein, though insufficient vitamin A would account for most, if not all, of the adverse nutritional signs noticed by the school medical officers The children appear to have become more unruly, noisier and naughtier and somewhat less well cared for, but there is no evidence at present that the war with its bombing, shelter life and disturbances due to migrations has had any great effect on child mentality

---

Letters to the Editor

CHARCOAL AND THE BP

SIR,—It gave me great pleasure to read your leader of June 27 exploring the physico-chemical basis of the pharmacological action of charcoal It has always seemed to me unfortunate that this drug should have fallen from medical grace and the BP at the moment when improved methods of activation had already raised it to a position of high esteem in industry The standard comment of its critics has been that charcoal, when wet, cannot adsorb gases efficiently For decades this scientific truth has been wrongly applied to conditions obtaining in the bowel and charcoal has been relegated to limbo despite the widely observed clinical fact that colonic flatulency is often substantially relieved when it is administered The two factors essential to success are the correction of the inherent constipating action of charcoal and the selection of an active variety Many activated forms are now available at small cost and for a few pence treatment could be continued for many days Therapeutic control over colonic gas is probably exerted before the gas is evolved Non-gaseous mother substances may be removed by adsorption or the gases themselves may be taken up in their nascent form before they have had time to coalesce and come out of solution as visible bubbles of gas

The reduction, during full charcoal therapy, in odour of the stool which is so noticeable is no doubt due not only to the removal of objectionable gases but to the adsorption of odoriferous liquids and solids such as scatole Charcoal may even prevent the formation of these bodies by adsorbing more complex precursors and removing them from their usual sphere of chemical interaction Adsorbents in general act also as catalysts, facilitating the interaction of substances simultaneously adsorbed on to their surfaces In this way more complete decomposition of bowel residues would be secured and the final products simplified

Charcoal is a powerful and useful substance of wide applicability in therapeutics and presently, I hope, with fitting stipulation as to potency and purity, it will be readmitted to the hierarchy of official drugs

London W 1 NATHAN MUTCH

MEDICAL WOMEN WITH THE FORCES

SIR,—In a previous letter, which appeared in your issue of April 18, regarding the status of women doctors serving with HM Forces, I stated that medical women volunteering for service under the Army Council were offered two alternatives—(*a*) relative rank with the RAMC without commission, or (*b*) a commission in the Women's Forces to serve with the RAMC—and that in the circumstances the Medical Women's Federation considered that " relative rank " only was preferable The federation has since been informed that medical women will not in future be permitted to choose relative rank without a commission, but must be given a mission in the Women's Forces—i e , they receive a commission in the Women's Forces to serve *with* the RAMC (A medical man receives a commission in the Land Forces to serve *in* the RAMC) We shall be glad *if publicity can be given to this decision in order to* avoid further misunderstandings

The position as regards medical women serving with the RAF medical branch has also now been clearl defined The women are obliged to accept commissions in the Women's Forces to serve with the RAF(MB) The appointments are gazetted as " to be medical officers with the relative rank of flying officer for employment with the RAF," and they are shown in the Air Force list as " Women medical officers commissioned for employment with the RAF "

CLARA STEWART,
President, Medical Women's Federation

TREATMENT OF RECENT WAR WOUNDS

SIR,—I hope it is superfluous for me to say that I agree with many of the views laid down by Professor Fruchaud in his paper of June 20, particularly with his four conclusions But I find some statements in his article which, I am sorry to say, are not in accordance with the facts

In the first place, Fruchaud writes of an exaggerated reaction against épluchage (wound excision) in the Spanish war In point of fact wound excision w recognised as the essential part of wound treatment in the army of Catalonia, and we made this principle our surgical gospel Secondly, Fruchaud makes a misleading statement when he says " The chief danger of imm bilisation in plaster, as practised by the Spaniards the treatment of war wounds, is that this compleme tary treatment may be substituted for the essenti operation " This suggests that we relied on the effe of the plaster more than on the operation, an implicati which is entirely wrong In my published work sin the beginning of the war in Spain, and even long befo it, I have always emphasised the vital part played b wound excision, and I am amazed to find how persistentl one has to stress the fact that the use of plaster for th treatment of accidental wounds is only permissible f surgeons who know how to perform a radical wou excision

From Fruchaud's article it is clear that his sole kno ledge *of the treatment of war wounds* in Catalonia w derived from the wounded soldiers whom he saw France at the end of the war Like the majority French surgeons, he was surprised to see that many the wounded had local infections, due, as he puts it, " insufficient operation " Is it not strange that o French colleagues should have been surprised at t number of local complications rather than at the va number of wounded who had survived the tragic en of an army which had retreated without a halt, from a area more than three hundred miles away ? Defea perhaps for the first time in history, was not accompani by an enormous increase in mortality Moreove casualties had been operated on in the most appalli conditions, often by the roadside and under continuo bombardment The surgeons who performed t operations tried only to enable the wounded to g beyond the range of the enemy, and thus in many ca the treatment was limited to a provisional enlargeme of the wound and the application of a plaster Th hoped that completion of the surgical treatment cou be carried out in France where the wounded wou arrive still in a condition sufficiently good for prop treatment It never occurred to my colleagues th many legs would be amputated on account of the b smell of the plasters It was a real tragedy that t teaching of the Lyons school—for which I have t greatest admiration—had no influence on the Fren surgeons who dealt with these cases during the first da after their arrival It is still more to be regretted th not a single French surgeon, with the exception Professor Ducuing, came to see our work during the w Had they done so they might have increased, if not th knowledge, at least their understanding of the fac The attitude of " It can't happen to us," for which are all now paying the price, if not confined to t French, was very prevalent among the surgeo

France right up to the time of that country's ollapse

One last word Without denying the important ontribution made by the modern Lyons school to the rogress of our profession it would not be just to attribute to that school alone the essential features of wound reatment which can be traced back far into the past, of them even to the school of Hippocrates

Oxford J TRUETA

SIR,—I read with great pleasure the article by Professor Fruchaud in the *Lancet* of June 20 He once more tates clearly and with the authority of experience the principles which should govern the treatment of war wounds To those in this country who direct the policy garding treatment of war wounds his words come as a sharp reminder that it is high time an authoritative statement were made as to the principles that should govern those who are called upon to deal with these njuries in the British Army The failure to organise teaching in wound treatment for Army surgeons, or even to state clearly the fundamental principles involved, means that men are being sent to the four corners of the earth to treat wounds without any clear knowledge of the correct procedure

Fruchaud warns us to beware of exaggerated enthusiasm for chemotherapy An even stronger warning should be issued against those who are laying emphasis on mechanical fixation of open and even closed fractures Incalculable harm will be done if recent discussions of this form of treatment and the emphasis laid upon it by those whose names suggest authority should lead to its adoption outside fracture centres or by the inexperienced

The technique described by Fruchaud differs in no essential detail from that advocated by Trueta The first " charge " he brings against the " Spanish method " is based on inaccurate information with regard to that method Trueta has always emphasised that adequate excision is the essential part of the treatment and the plaster complementary. The second is a detail of relatively minor importance The ideal method of producing the desired immobilisation of the tissues is the well-moulded, skin-tight plaster A dry gauze dressing loosely placed in the wound, in contact with highly absorbent plaster, provides the best method of drainage Both these statements are true only if adequate excision of the wound has been carried out and counter-drainage established when necessary Modification of the technique must be adopted to suit the local conditions

The last four sentences of Fruchaud's paper point a moral as important in the surgery of war wounds as is the dive bomber in the conduct of the war.

Radcliffe Infirmary, Oxford J C SCOTT

REACTIONS TO THE REPORT

SIR,—For many months a study group has met each fortnight in Tunbridge Wells, and this seems an opportune moment to bring to the notice of the profession certain considerations which appear to us fundamental, and should be borne continuously in mind when the interim report of the Medical Planning Commission is being discussed Too much thought has hitherto been given to details and not enough to principles

All persons regardless of class and wealth must have identical and complete medical facilities made available to them

The majority of the public is only too aware of the many shortcomings of the medical services available to it, and though the public is a bad judge of what is good for it, yet its parliamentary representatives are fully cognisant of these shortcomings and intend to remedy the position at the earliest opportunity

The almost unlimited gap between curative and preventive medicine must be bridged, for planning the future must concern itself largely with the preventive aspect of medicine, even though the education of the profession itself has been almost exclusively concerned with curative medicine

Research of all kinds needs adequate financial support and coördinated effort, not only nationally but internationally

The lack of coördination and coöperation in the existing medical services has resulted in an enormous waste of money, men and material, as well as giving rise to an ill-conceived and often ill concealed hostility between the GPs, the school medical officers, MOHs, &c

Improvement in the general health of the nation is impossible by medical means unless at the same time there is an improvement in environmental conditions , malnutrition and bad housing are the signposts of disease, disaster and death

The education of the public in health matters has been woefully neglected, with the result that the public has been far more concerned with the curative and palliative aspects of medicine—much to the benefit of the purveyors of quack medicines and remedies—than with the preventive , this aspect should therefore be continuously put before the public by all legitimate means of propaganda

The medical profession has failed to give an intelligent lead to the public and as Gregson wrote, " the profession must forsake its attitude of isolationism and take its place as a driving constructive force in remodelling the post war world " The profession now has its opportunity and must urge that better conditions for the masses is an essential part of its responsibilities, for the minimal standards of nutrition, working hours, working conditions and satisfactory housing are now known This is our moment , let us have vision beyond tomorrow and build worthily for the future

Tunbridge Wells W O MOORE EDE

SIR,—The " Majority ' Scheme of the BMA Medical Planning Commission will be unacceptable to a great number of medical men who can see in it a stepping-stone to a whole-time state medical service in which the freedom of the doctor and patient would disappear It is disturbing to know that, at this time when we are fighting a country in which state socialism dominates everything and everybody, and when that freedom both national and individual which we have enjoyed for so long is in dire peril, schemes are being put forward by our own countrymen to deprive the medical profession of its traditional professional freedom Many of us have no wish whatever to see the profession become a branch of the Civil Service, which is receiving so much criticism at this time on account of its bureaucratic tendencies and lack of initiative

Surely it is quite wrong to suppose that state control would improve the health of the community, and make the medical profession more efficient We need not burn down our house in order to obtain improvements An extension of the present system (roughly on the lines of the original BMA grey-book scheme) is all that is really necessary or desirable In London and large towns there is no difficulty in obtaining expert advice, special examinations or treatment Communal surgeries or health centres are not necessary Consultations between doctors can be easily arranged without these polyclinics It would be disastrous to try and regiment the profession and the medical services Uniformity is not desirable and the disappearance of voluntary hospitals would be highly regrettable Private practice must be allowed to continue if doctors are to retain their freedom It is a fallacy to suppose that society can ever be classless Equality can never exist in company with freedom Freedom of choice on the part of patient and doctors is essential The sale of practices is just as legitimate a transaction as it ever was

We have no reason to be defeatist or to follow alien models Improvements in medical services must be evolutionary and based on British traditions which have always placed high value on individual freedom and individual enterprise It is suggested that a doctor under a state service would be moved from one place to another, whether he wanted to or not Many of us have lived for years in the locality we have chosen ; we have got to know the people and take a great delight in our homes This would be the very negation of freedom and would constitute a grave injustice No compensation in the form of pensions could make up for loss of freedom

These, Sir, are only a few of the objections to a state service, whether partial or complete, and it is difficult to believe that the majority of medical men would really welcome such a scheme if they realised its implications

FOR EVER FREEDOM.

SIR,—As a practitioner of close on 30-years standing and the fourth in the line my great grandfather having subscribed to the first number of the *Lancet*, may I make a few comments on the Medical Planning Scheme ? Although professing not to be a whole-time state medical service, it is nevertheless a compromise and a forerunner of the whole-time service to come Those of us who value our individuality and freedom feel that the more acceptable scheme would be an extension of the present NHI system bringing in dependants and a consultant and specialist service A fair and adequate capitation fee should be paid and there should be a pensioning scheme and opportunities for postgraduate work I do not believe the majority of patients, panel or otherwise, wish to see their doctor at a polyclinic Collective medicine may suit some countries but it is unsuitable for this England of ours The people prefer to see their doctor in his own surgery and in large towns the doctor can *already send his patients to see a specialist at a* clinic in hospital, often by appointment

Why abolish buying and selling of practices ? Is this evil ? Have the gentlemen of the law done so, and do *they* propose to place themselves under the state ? Many of us have sunk considerable capital in our practices—capital obtained by hard work and savings Is this evil ? Nothing can compensate us for the loss of goodwill and for our individual freedom As for competition, surely this is a good thing A doctor under the present conditions of medical practice soon loses his patients if his work is not up to standard Leave the practitioner alone and do not turn him into a civil servant with the attendant evils of bureaucracy Free choice of doctor and an opportunity for private practice in the fullest sense of the word are essential

PS—It is surely unfair to revolutionise medical practice when so many practitioners are away on service and will have little or no say in the matter.

Gloucester Gate, W 1 RUSSELL STEELE

PSYCHOLOGY AND CHILDBIRTH

SIR,—With the recent experience of the birth of my first baby still very fresh in my memory, may I be allowed express my appreciation of such teachers as Dr nest Jones In anticipating my own pregnancy and nfinement, my postgraduate midwifery training in ospital and my experience in general practice left me eeling that I, as an average practitioner, had known next to nothing of the psychological features of childbirth I happened to find Dr Grantly Dick Read's "Natural Childbirth," and this was my source of inspiration during pregnancy The results of following this teaching have been highly satisfactory, from all angles Dr Scott's objections seem to me to indicate again that certain of us tend always to be less aware than the others of the underlying reasons for our attitudes The observations of the "majority of psychologists" cannot be so easily dismissed

Glasgow MARY MACK

WHAT IS A CONGENITAL SYPHILITIC ?

SIR,—Dr Nabarro in your last issue (p 778) makes the tacit assumption that syphilis can be transmitted to the third generation without a fresh infection Many other experts share this view, but personally I have never been able to satisfy myself that the evidence adduced is scientific, for the fact that a woman labelled a congenital can produce a syphilitic child is not positive evidence at all, if one stops to think of the two main assumptions implied

The first assumption is that every syphilitic baby is a congenital Now it is wise in any discussion to define one's terms, and I would define a congenital as a child infected with syphilis in utero Unfortunately however there are also large numbers of children born healthy but infected at or soon after birth by their syphilitic mothers These are not *congenital* but *natal* syphilitics Though Colles's law is true that a syphilitic child cannot infect its mother, the converse unfortunately is not true and a syphilitic mother can infect her healthy child at birth (or after birth) by handling, nursing or suckling All these natal syphilitics so infected are really acquired, and that they may produce congenital syphilitic children in the next generation is quite possible, especially if they marry early enough

The second assumption is the chastity of the mother People who produce congenitals are not generally of the highest moral calibre There is always some doubt about paternity, and the fact that a congenital child is born to a congenital mother and a supposed father who is Wassermann negative is no legal proof of transmission without reinfection Cherchez l'homme is as important cherchez la femme in a problem of this nature

Direct proof is obviously a matter of extreme diffi The ideal experiment would be to maroon two conge on a desert island, let them have a child, make that the child's blood-group was compatible with that the supposed father, and that there was no lur beachcomber hiding in the palm-trees in the back to complicate the issue If the child so produced out to be a congenital, I would be inclined to accept as positive proof of hereditary transmission to third generation But knowing the frailty of human *nature and the complete unreliability of the* history given in most cases of venereal infection I should hesitate to accept any less stringent proof

Wimpole Street, W 1 J JOHNSTON ABRAHAM

CONSIDERATE TONSILLECTOMY

SIR,—Welcoming as I do any kindness to a patient before and after operation which does not increase it risk, I would like to emphasise some of the points in your leading article of June 27 Even if a child is kept in hospital for one or two nights after its tonsils have been removed, there is still the risk of broncho-pneumonia from the journey home in inclement weather It is therefore best to shut down tonsil operations during the winter, say from the middle of November until the end of February If it be thought essential to remove tonsils during this close season, transport home should be provided from door to door Two further precautions will go far to prevent this and the dreaded post-tonsillectomy mastoid Do not take out tonsils from any child that has had measles, scarlet fever or whooping cough, wait until the next following spring Do not take out tonsils during a measles epidemic from a child that has not had measles That post-operative supervision should be adequate and skilled all will agree, but we may differ as to what it should be To have any attendant sitting by the patient is to my mind a mistake The child should pass from narcosis into natural sleep, if he opens his eyes to see an adult standing over him, he will open them again, take notice and sit up There should be no hope or expectation at the bottom of his little mind that mummy or daddy may be there This is done by talking *to* the [illegible] but *at* the child, when the operation is being a[illegible] Tell the mother that she will bring the chi[illegible] hospital in the afternoon, that the operati[illegible] done at a certain time next day, preferably th[illegible] but that she will not be allowed to see the [illegible] 5 P M and then only a peep Make it quit[illegible] her presence in the hospital is not needed ei[illegible] or after the operation Some mothers will ref[illegible] away, it is their children who will wake [illegible] and then will need an attendant by the bed[illegible]

My last point is that the time taken to de[illegible] against the operation should never be less than [illegible] of an hour A mother is entitled to that amou[illegible] surgeon's time at least before she commits [illegible] into his hands. Mr Gerrie and Dr Ross M[illegible] state "In a busy hospital time is of great impo[illegible] but all they deplore arises from the implication[illegible] statement, and the whole history of surgery s[illegible] introduction of general anæsthesia is a contradi[illegible] it The late Sir William Milligan thought it w[illegible] remove a child's tonsils in less than twenty [illegible] and no-one was a more rapid operator than he [illegible] siderate tonsillectomy" begins with the cons[illegible] and "humanity in dealing with the nation's c[illegible] must take precedence over the surgeon's time [illegible]

Guy's Hospital, S E 1 T B L[illegible]

PAIN IN PEPTIC ULCER

SIR,—Your leading article of June 13 interes[illegible] very much In all articles on this subject or [illegible] healing of peptic ulcers I have seen no referenc[illegible] effect of jejunostomy on the relief of pain and sul[illegible] of ulcer symptoms, yet in my experience this pro[illegible] gives relief in a few days In 1933 I described tw[illegible] in which I had used jejunostomy when encou[illegible] such severe ulceration with accompanying œdem[illegible] adhesions that a partial gastrectomy would hav[illegible] impossible in so severely ill patients (*Brit med J* [illegible] i, 221) Since then I have resorted to the same pro[illegible] in five other occasions, resulting in relief of pain, healing the ulcer, subsidence of all inflammatory reactions and solving of massive adhesions so that after two to three months a partial gastrectomy became simple In these cases the patients were fed entirely by the jejunostomy, taking nothing by mouth save only water if they found it essential though they seldom did No alkalis were given The pain of an acute exacerbation of an ulcer can be relieved by a Ryle's tube and repeated aspiration, while feeding is done by intravenous glucose saline This amounts to the same as the jejunostomy but cannot of course be maintained for so long

Surely these methods produce *true* rest for the stomach as against that alleged to be produced by repeated small feeds Hunger contractions are prevented because the patient is fed—in other words, an empty stomach will be at rest provided the body receives its nourishment through other channels From this it seems to me that the ulcer pain is due to muscular contractions plus inflammatory changes In jejunostomy the muscular contractions are relieved first, followed as a result by subsidence of the inflammatory changes This explanation would account for the immediate partial relief, followed in a few days by complete relief, and is in accord with the healing of ulcers in other parts of the body.

It would be interesting to know if experiments have been conducted on these lines and if others have used jejunostomy in this connexion

Portsmouth O STANLEY HILLMAN

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS M P

LAST week opened explosively with demands for the presence of the Prime Minister in the House to answer questions and debate the situation arising from the defeat of the 8th Army in Libya The next day there was a debate on the colonies in which Mr H Macmillan described a three-pronged war policy; the increased production of things we need—that is notably vegetable ts and minerals—the restriction of imports to the onies and an increase of food production West ca is concentrating on rice, vegetables and dairy uce, and as milk has been an import from Great ain to West Africa the change is revolutionary In Africa the food increase is in wheat, maize, rye and nd forced labour is being used The extent of changes in food production can only be estimated ifficulty but they should produce at least some of permanent value to the level of nutrition in pics

H. B Morgan forcibly drew attention to the le poverty of the West Indies—children naked able to attend school, primary venereal disease young children treated at open clinics, and the rable condition of the West Indian colonial service "There is," said Dr Morgan, "only one Barbados Island with a population of 200,000 and she was only appointed in 1939" He asked heme to train West Indian nurses in London

* * *

important debate on family allowances was overed by these multifarious activities but may lead portant results Unfortunately the first form motion had been whittled down, by arrangement ough the Government, to a resolution commending the ion of a national scheme to the immediate conon of the Government As a white paper on allowances has already been published it is to umed that the Government have some cognisance scheme But anyway the etiolated resolution ved by Wing-Commander J A C Wright and ded by Miss E Rathbone who is so largely responsible ging the scheme forward as a practical and eable plan Miss Rathbone in 1925 wrote "The erited Family," which focused the attention of ists and those concerned with the importance of amily in society on the allowance problem In 20's New Zealand and New South Wales adopted The federal government of Australia and the ment of nearly every country in Europe instituted allowances for their civil service Miss Rathbone said that to bring about any social reform in this country one needed the patience and perseverance of Bruce's spider, the importunate widow, the Ancient Mariner and the giant Sisyphus rolled into one She laid stress on the statistics of Mr Seebohm Rowntree's book on Poverty and Sir John Orr's computation that a quarter of all children belong to families where the total income works out at 10s per head per week "And yet when a maximum price of 5s is put on a restaurant meal, we call it austerity" The speech had passion behind it and she begged the Government to give hope of an early scheme And the Chancellor of the Exchequer did give some hope of a scheme being considered in the autumn in the light of Sir William Beveridge's report, the Trades Union Congress in September and of our financial position But the reply was on the whole disheartening and the prospect of effective action in the near future not very great But members are uneasy that they have to turn their minds away from these fundamental problems to immediate dangers And in that uneasiness is a tribute to Miss Rathbone's work and the sure belief that her work will in the end be realised

FROM THE PRESS GALLERY

Family Allowances

THE supporters of family allowances are no longer a minority forcing an unwelcome proposal on the Government but rather a majority giving expression to an enlightened social conscience In moving the institution of a national scheme in the Commons on June 23 Wing-Commander J A C WRIGHT pointed out that parenthood is both a privilege to the individual and a service to the community and that the benefits of family allowances will accrue to the nation rather than to the individual The greatest single factor in poverty is the size of the family and we can best honour the family by helping it, but the scheme could not be successfully run by what he called the "soup-kitchen" mind, for it should not be regarded merely as an antidote to destitution Once settle the principle of family allowances and the task of the Beveridge Committee on the reorganisation of social insurances would be enormously simplified Miss E RATHBONE dared to be impatient for the sake of the children and asked how many generations were to grow up with stunted bodies and minds while political parties were letting "I dare not" wait upon "I would" She pointed out that even the target of school dinners for a million children would only cover a fifth of the elementary-school population Family allowances would relieve the children from want and their parents from fear Mr M R HELY-HUTCHINSON asked to be allowed the luxury of a little debunking Destitution was accentuated by large families; it was not always or necessarily caused by large families He contended that while there might be a case for allowances for those below the average or desirable income level there was no case for a general scheme Dr EDITH SUMMERSKILL has found the well-fed child is the alert, receptive child, and she predicted that if the standard of living of our child population was improved there would be a rapid decline in juvenile delinquency She had been impressed by the BMA scheme for a medical service for everyone after the war but let Parliament see that each child received a bottle of milk before it received a bottle of medicine Mr F MONTAGUE sharply criticised the scheme from the point of view of a Socialist He believed in direct social service —such as free education—but not in subsidies If they wanted to solve the problem of nutrition, they must take the elements of nutrition right out of the money economy The people required so much as a standard of nutrition The amount was known Let Parliament guarantee that minimum to the whole of the nation as a foundation of its physical existence Captain C YORK speaking as one of the younger generation, advocated a five-bob a nob scheme for every child, rich and poor alike, and the elimination of the present income-tax allowances

Sir KINGSLEY WOOD admitted that the case for family allowances was powerful, for it would lessen the risk of malnutrition in large families Support in all sections of the nation had steadily grown, and while it was true that family allowances were not strictly within the terms of the Beveridge Committee, any scheme must obviously be considered in conjunction with the report from that

OUTBREAK OF SMALLPOX

ON May 29 a ship arrived at Glasgow with a case of illness that was there diagnosed as variola major The infection was probably acquired at Cape Town There were on board about 1200 persons, civilians and service personnel, all of whom were vaccinated or revaccinated on May 29 They proceeded to their destinations and medical officers of health of the districts concerned were informed Of 12 contacts, regarding whom particulars are available, all except 2 were successfully vaccinated while they were incubating the disease and the attacks were modified In one case the vaccination was unsuccessful and the child, who had never previously been vaccinated, developed smallpox in Swindon where it had been taken Two cases in Swindon residents have since been notified In Glasgow there has been a spread of the infection, and 14 residents have been removed to hospital, the latest admission being on June 29

According to the most recent information 12 members of the ship's company were removed to a smallpox hospital in Glasgow and 2 of these have died, 14 persons resident in various parts of the city have been removed to hospital as definite cases of smallpox, and 3 cases have been notified in Swindon The total of known cases is therefore 29

University of Cambridge

At recent examinations for the degrees of M B, B Chir, the following were successful —

Part II—Surgery, Midwifery and Gynæcology J N Agate, R J Alcock, W B Alexander, A G S Bailey, A D Barlow, H W A Baron, D J Bauer A O Bech, C P Bennett N L Birkett, F W Blacklay, R J K Brown P H Buxton, T O Candler, A W Capon, E F Carr F S Carter, J M Childs, J A H Collyns D J Conway, W N Coombes, P N Cunliffe A J Danby, I N Darbyshire, J Dean, P J R Deller, W K Douglas, M P Durham P F Early, A G Eddison (W F Felton, J H L Ferguson, J L Fluker, T R Gilchrist, J V T Gostling, A G Harrold P L M Hartley, D Hilson, T S Hindle, R F Hollick, S C H Hood P H S Hooper, E N M Johnston, H R Jolly L G Kingdom W S S Ladell, F M Lancaster, F K Lau T L T Lewis, D I Lishman, G C Lloyd Roberts J Lomas, F H Lomax, T G E Loosemore, D McAnally I M MacArthur, F L McDonald N M Mann, H E S Marshall, P H N Matthews, R M S Matthews, H R A Michelmore, P A G Monro, W K S Moore, J M Morgan, Y H Ng, W J L Pain, J S Pegum, J A Peters, R V Peters, H L Pierce, R J F H Pinsent, B Pownall, E Pringle, S H Purser J F P Quinton, R K Reid, W Rogers, L A Rook, H M J Rowan, I A Roxburgh, P H Sanderson D L Sandes O L S Scott T O Scudamore, J H Simpson, I M Smith O Sookias, J W Squire, J H Steeds J P Stephens H C Still J R Thompson, R N Ticehurst, W H Trethowan G S Udall, C R M Warner, D J Watt, L A S White, E N Whitley, D E C Whittome, A B Willcock, and H I Winner

Diphtheria Returns

The Minister of Health has asked medical officers of health to let him have, as soon as possible after June 30 and not later than July 21, their returns of the number of children in their district immunised against diphtheria during the last six months They are also asked to give figures for fatal cases of diphtheria in children as well as notified cases, but detailed particulars about each notification are no longer required

Oxford Nutrition Survey

The Rockefeller Foundation has made a grant of £1875 towards the expenses of this survey during the past year and has promised a grant of £3000 for each of the next two years These funds will be administered by a committee consisting of the Regius professor of medicine, the Whitley professor of biochemistry, the Waynflete professor of physiology, Sir Robert McCarrison, Sir Wilson Jameson, and Dr H M Sinclair The survey is investigating economic, dietary, clinical and biological methods of assessing nutrition in man Besides giving training in their use it is also on behalf of the Ministry of Health examining the nutrition of samples of the population

Socialist Medical Association

At their annual general meeting on May 10, the association passed a number of resolutions dealing with problems of our war time world While they concur in the need for mass X ray examination of susceptible groups, they regard the provision of more adequate NHI benefit for tuberculous patients as an essential part of the development of any scheme of this kind They welcome the inclusion of tuberculous ex patients in the Ministry of Labour rehabilitation scheme, but urge the establishment of the principle of subsidised wages for part time or substandard work They are concerned at the deterioration of conditions in mental hospitals as exemplified by the increase in the incidence of pulmonary tuberculosis, and ask the Ministry of Health and the Board of Control to release beds requisitioned by the EMS or provide alternative accommodation, to examine by mass radiography at regular intervals patients and staff, and to arrange for advice by local tuberculosis officers in early selection of cases The association also suggest that all restrictions on the use of EMS hospitals imposed by local government boundaries should be overruled and that these hospitals should be free to accept patients from any area, but particularly from that in which they are situated The association call for the reservatio of doctors now in industry and for the direction of furthe doctors into industry, but suggest that for the treatment o minor ailments more use must be made of the industrial nurse and of the welfare worker They also recommend the setting up of committees in hospitals and public health departments similar to the production committees of industry on which both employers and employees are represented

Royal College of Physicians of Ireland

The following have been admitted to the fellowship of the college J A D Deeny, MD, Lurgan, co Armagh, Andrew Whelton, MD, Cork, and John Duffy, MD, Dublin

London County Council

The council, at its meeting on June 30, passed a resolution regretting the exclusion by the Minister of Health of mental nurses from consideration by the Rushcliffe Committee for the national determination of nurses' salaries

Dr D Stark Murray has been appointed a member of the hospitals and medical services committee

Medical Casualties

In a recent casualty list it was announced that WS/Captain S A H Qureshi, MRCS, RAMC, has died T/Major E E Evans, LMSSA, RAMC, has been posted as wounded, and Captain Conrad Rigby, MB Lpool, RAMC, has been officially reported as missing since the fall of Singapore

Research in Transfusion Products

The trustees of the late Sir Henry Wellcome have placed a sum of up to £20,000 at the disposal of the Medical Research Council for research into methods of drying blood plasma and blood serum to provide stable products for use in transfusion The gift is to be applied to the purchase, erection and operation by the council of a plant which will make it possible to test and develop these methods on a substantial scale, and the products will be freely available for the treatment of sick and wounded at home, at sea and abroad

Appointments

BOTTOMLEY, JANET FRCS senior house surgeon at the Chel Hospital for Women

MACGILCHRIST, D C, MB EDIN examining factory surgeon f Duns and Chirnside, Berwickshire

MARSHALL STANLEY MD LOND temporary pathologist at th Hospital for Consumption, Brompton

QUINNELL, G A F, MB GLASG examining factory surgeon f Milborne Port Dorset

Births, Marriages and Deaths

BIRTHS

BRIGSTOCKE —On June 25 at Norwich, the wife of Captain Mervyn Brigstocke RAMC—a son

HEESOM —On June 25, at Reigate, the wife of Dr Alan Heesom—a daughter

JEFFERISS —On June 22, in London, the wife of Major Den Jefferiss, RAMC—a daughter

LANCASTER —On June 24, at St Annes on the Sea, the wife o Capt Geoffrey Lancaster RAMC—a daughter

McSHEEHY —On June 21 at Woking, the wife of T/Major H O F McSheehy, RAMC—a daughter

STUART HARRIS —On June 22, at Andover the wife of Ma C H Stuart Harris RAMC—a son

SWANSTON —On June 18, at Thirsk, the wife of Dr Kelly Swans —twin daughters

MARRIAGES

ALMOND—WARD —On June 20 in London, Richard Geo Patrick Almond, Surgeon Lieutenant RNVR, to Ursula War WRNS

BAKER—COLLINS —On June 26 at Heathfield, Sussex, Co Baker MRCS, to Betty Collins

DAVIES—BROOKS —On June 13, at Lowestoft, T Tibbott Dav Surgeon Lieutenant, RNVR, to Jean Brooks

HARRIS—BARCLAY —On June 20 at West Malvern, St Geo Eyre Harris, OBE, RAMC, to Mary Kathleen Barclay, CBE, R late QAIMNS

LEE WOOLF—McKENDRICK —On June 20, at Oxford Ja Philip Lee Woolf, BD, to Jean Dorothy McKendrick MB

WILSON—PALLISTER —On June 24 at Lambeth, Richard Wil Lieutenant, RAMC, to Barbara Pallister

WOOD—BERWICK —On June 20, at Compton, Louis Art Charrington Wood Captain, RAMC, of Penshurst, to Mar Berwick, of Bournemouth

DEATHS

HALL —On May 12 at Esher, Frederick William George Gor Hall, CB, MB EDIN, colonel, AMS retd, aged 80

ÆTIOLOGY: A PLEA FOR WIDER CONCEPTS AND NEW STUDY*

JOHN A RYLE M D LOND, F R C P
REGIUS PROFESSOR OF PHYSIC UNIVERSITY OF CAMBRIDGE, CONSULTING PHYSICIAN, GUY'S HOSPITAL, CONSULTANT ADVISER EMS

BY ætiology we should understand the science, not of cause, but of causes The Oxford English Dictionary defines it as "the science or philosophy of causation," and Dorland's Medical Dictionary as "the sum of knowledge regarding causes" It is well to insist on such definitions, for the discovery by Pasteur and the great pioneers in bacteriology of specific microbic agents of disease, and the recognition by others of specific chemical agents and specific deficiencies have, until quite recently, and contemporaneously with their immense benefits to medicine, had a peculiarly limiting effect upon the vision and the practice of many medical men, not excluding teachers They have in fact compelled a neglect of the associated causal factors without which no disease can have its being They have also fostered a belief in or search for single determining causes where none exist For the most part specific factors appear to have a greater importance in acute than in chronic diseases, but even here they would be inoperative but for the conspiracy of other factors, the discovery of which is essential to the full understanding of individual liability and pathology For example, the pneumococcus may be essential to the development of lobar pneumonia, but seasonal and climatic conditions, poverty and other environmental accidents, and inborn susceptibility—to mention only a few associated causes—can also play their part Susceptibility again is often related to age sex, physical type and habits Factors of this kind have suffered neglect through preoccupation with ideas relating to the microscopic organism which we accept and name as the *causa causans* of the disease Some of them especially, as the *causæ causarum* of disease await our more intimate study.

* * *

When we come to consider such chronic diseases as duodenal ulcer or pernicious anæmia, diseases for which no research up to date has revealed a constant mode of causation, the concept of "multiple factors" is of even greater importance and can influence not only academic interest and understanding, but also our bedside assessment and management of cases At the end of the last war we were still under the domination of the bacterial hypothesis and seeking to attribute peptic ulceration (and indeed many other unrelated diseases) to infection having its origins in some remote focus such as a tooth socket At the beginning of the present war a deepening and healthy interest in ætiology has led us on (or back, for the older physicians were very alive to these causal complexities) to the "multiple factor" hypothesis and the concept of focal sepsis as a main contributor has been largely discarded In the case of duodenal ulcer we are accumulating evidence, through careful inquiry into natural history, for the part played in pathogenesis by such factors as age, sex, hereditary predisposition, physical type and temperament on the one hand, and emotional and occupational stress and tobacco on the other Under the influence of one or more of the last three factors (which somewhat similarly affect the neuromuscular behaviour of the stomach) it may be suggested that there are persons endowed by one or more of the preceding five factors with a heightened susceptibility (in association locally with an innate tendency to motor, secretory and vascular overactions) to the development of the characteristic lesion Diathesis and environment, through sustained physiological disturbance, both have significant influence and may even provide the "whole cause" The story is not complete, but we begin to see the plot

At the end of the last war we were wholly in the dark as to the cause of pernicious anæmia Dental sepsis was again principally blamed and its importance re-emphasised by Hunter (1890, 1922), while Hurst (1923–1924), Faber (1924) and others insisted, with better but incomplete justification as time has shown, on the contributory influence of the accompanying gastric achylia The brilliant discovery of Minot and Murphy (1926) and the researches of Castle (1929) not only revolutionised treatment and relieved a mortal disease of its baneful name and prospects, but have led us far along the path of a true pathogenesis which is again shown to be based on varying "multiple factors" Age-incidence was recognised and an associated physical type commented upon by Addison (1849–1855) who, although Combe had reported a case in 1822, was the first to give full and separate portraiture to the disease The probable gastric pathology and the community of Addison's anæmia and subacute combined degeneration of the cord have been stressed by Hurst. Familial liability has been demonstrated The correction of the symptoms by an extrinsic food factor and the appreciation of their dependence upon the lack of an intrinsic factor, which we owe to Minot and to Castle together with other studies, have now taught us that deficiency in hydrochloric acid is not a cause, but that a certain type and distribution of gastric mucosal injury promoting another secretory deficiency is the usual precursor of the spontaneously developed blood-disease Clinical inquiry activated by these discoveries has also shown that carcinoma of the stomach or sometimes the operation of gastrectomy, and tropical sprue and other diseases of or operations on the small bowel may also be followed by Addisonian anæmia Healthy persons, free from any of these antecedent gastro-intestinal pathologies, do not develop anæmia on diets deficient in sources of the specific extrinsic factor Addison's anæmia thus becomes an example of what is now termed a "conditioned deficiency" disease. It may depend either upon lack of intrinsic factor when the stomach is at fault or upon an absorptive defect when the small bowel is diseased or resected In the first instance peroral administration of extrinsic factor is effective, in the second it must be given parenterally Not a single determining cause, such as we were seeking twenty years ago, but a varying conspiracy of causes is the truer ætiological picture A specific deficiency may, it is true, be claimed as the ultimate and essential factor, but it is due to and only effective in conjunction with a variety of other factors and some of these must be held to have at least an equal importance with the deficiency itself in promoting the arrival of the disease

Directly influenced by this new knowledge we are now becoming familiar with the occurrence of other conditioned deficiencies and avitaminoses arising generally as a consequence of some preceding gastro-intestinal pathology Examples are the peripheral neuritis of alcoholism, pellagra complicating cancer of the stomach and the multiple mineral deficiencies and avitaminoses accompanying tropical or non-tropical steatorrhœa Thus it comes about that deficiency diseases, due usually to grave dietary restrictions attendant on geographical chance or war and famine, can also occur from time to time in any place or clime and even when full diets are available

* * *

And then there is the case of cancer Whatever new knowledge may emerge from the various intensive studies so long and so patiently pursued in so many laboratories it appears probable (alike to its clinical observers and its experimental students) that this disease too must come to be classified among those dependent upon variable "multiple factors" Herein reside some of its chief difficulties In all the more chronic types of disease—whether infective or neoplastic—it would seem that the several factors concerned possess a much more equivalent influence (as is suggested by the story of Addisonian anæmia) than is usually the case with the acute diseases Typhoid fever, it is true requires a chain of accidents to bring it into being in the individual, but with a given dose of organisms it could probably be produced in anyone who has not been inoculated or previously infected with the same organism For many reasons the liability to pulmonary tuberculosis is much more variable, the parts played by such attendant circumstances as age, nutrition, occupation and family predisposition clearly have a more equal value in comparison with the bacterial invasion than have like factors in comparison with an invasion of typhoid bacilli Nor need we ascribe the different liabilities entirely to differences in the number, type and mode of action and spread of the invading micro-organism. Thus in tuberculosis, youth and bad nutrition might be said to have equivalence with a certain dose of tubercle bacilli as determining factors in the precipitation of the disease Neither a more mature and resistant age nor good nutrition, however, might protect against a particular dose of typhoid bacilli shown capable of producing the disease in a starved child

---

* Part of the Dr Isaac Gilchrist Lecture on "The Progress and Present Aspects of Medical Science' given at Aberdeen University on June 10 1942

Passing again from these acute and chronic bacterial diseases to cancer we know that age in most cases, and sex and chronic irritation affecting certain organs or tissues in some are ætiological factors which cannot be disregarded It may even be suggested as likely that age and chronic irritation (through waning tissue activity) and sex (through changing hormonal balance) will be found to have an equivalence as determining factors with such specific agents as are brought to light by the experimental method and animal studies

* * *

Pursuing our argument a little further, it becomes apparent that a specific factor is one which determines the species, kind or nature of a disease As such it is a sine-qua-non It is no more the determinant of the arrival or the amount of a pathological change than are some of the other factors concerned This definition, however, does not imply that specific factors lack quantitative variations and effects The relatively stronger effect in the chronic than in the acute diseases of such non-specific factors as age, sex, habits and occupation is clearly in part a " temporal " one and due to sustained influences To such influences the quick tempo of the acute diseases allows little or no play. There is therefore, as has been indicated, fuller justification in the chronic than in the acute diseases for invoking the " multiple factor " hypothesis

The ætiology of the psychosomatic disorders and of the visceral neuroses in particular is now being more fruitfully studied, but here too much error remains to be contested From the end of the last war and before to the beginning of this there has persisted a vagueness of thought and laxity of judgment in connexion with the disorders of the hollow viscera The heart, in spite of the influence of Mackenzie, Wenckebach, Lewis and others, has continued to be labelled with the name or suspicion of disease in countless cases in which its behaviour was only expressing emotional or environmental stress The abdominal organs have been repeatedly subjected to exploration or operation for symptoms due to similar causes The crude idea that pain of necessity implies a lesion, the over-mechanistic influence of surgery—so potent in certain anatomical adjustments or the eradication of grossly diseased parts—and the increasing safety of surgery and anæsthesia are largely responsible Neglect of the important work of Cannon and Pavlov, neglect of careful history taking and temperamental assessments, and the temptation, in the face of a difficult symptom-analysis, to hand over the investigation of cases to the radiologist or the chemist have also played their part Constitutional and nervous causes, social circumstance and habits of life have in the meantime been undervalued and too superficially investigated

* * *

Ætiological study, although it may require and be grateful for the assistance of physiology, genetics, and experimental pathology, is essentially a clinical or " field " study in the first instance It is based on observation and historical analyses It is a part of medical science It has suffered neglect, curiously enough, in the past quarter of a century through the influence of new discovery which should have helped it It has been coming back into its own in the past few years It has important contributions to make to preventive as well as curative medicine If clinical teachers and students and practitioners will continue to welcome and extend its discipline, they will inevitably find that the interest of their subject is enhanced and that judgment in practice benefits

Of all the functions of ætiological science, in its broader practical applications, the most important are the recognition and more intimate study of those factors in their work, nutrition and housing, which at present take such a heavy toll of the life, health and efficiency of the working classes in all countries Indeed much that is truly ætiology extends beyond the relatively co province of pathology and invades the broader territory of social science.

Francis (1942) recently reported the spread of a type 12 strain of hæmolytic streptococcus in a plastic-surgery ward during the first nine months of 1941. The strain was insensitive to the sulphonamide group of drugs Its appearance in the wounds was frequently associated with acute sepsis Towards the end of the same period there occurred a series of cases of sepsis, similar in their clinical manifestations (fever, suppuration, sometimes an " erysipeloid " flush, &c), but differing sharply in their bacteriological findings No hæmolytic streptococci were grown from these cases, either aerobically or anaerobically, and the predominant organism in each case, in films and cultures, was a non-hæmolytic streptococcus Thirteen patients up to date have yielded streptococci of this type from a focus of infection , some had little or no fever

In one case acute sepsis followed a plastic operation involving a healed scar Non-hæmolytic streptococci had been isolated from the wound several months before but had not been investigated

In another case sepsis followed a plastic operation involving an unhealed wound from which similar streptococci had been isolated on three occasions within a few weeks of the operation—but again these cocci had not been investigated

In a third case a large raw area resulting from excision of the breast had yielded hæmolytic streptococci (type B3264), but these had disappeared under local treatment with sulphanilamide prior to operation for covering the wound After the operation only non-hæmolytic streptococci could be recovered and the patient became extremely ill

In a fourth case a patient suffering from burns died from endocarditis Non hæmolytic streptococci, reacting as group A, type 12, were isolated from the spleen post mortem and also from some of the burnt areas and the urine during life

In two other cases the acute sepsis did not follow operative interference Non hæmolytic streptococci had been recovered before the flare up

In five other cases the sepsis was slight, with little or no fever, but the clinical course was more or less unsatisfactory

One of the two remaining cases is noteworthy in that the organisms were recovered from a septic wound of the buttock on admission from another hospital

BACTERIOLOGY

The thirteen strains isolated from these cases had few distinguishing features With two exceptions the colonies on blood agar were matt and of similar size, conformation, and consistency to those of ordinary group A hæmolytic streptococci—although growth at 37° C was somewhat slower The two exceptions—strains subsequently identified serologically as types 11 and 25 respectively—gave glossy colonies None of the thirteen strains showed the " curled leaf " appearance which is so characteristic of hæmolytic streptococci on certain media, but this feature was very inconstant with the blood agar we have been using

There was neither α nor β hæmolysis on the primary cultures made with horse blood agar (meat infusion medium supplied by Major McCartney) aerobically, nor with subcultures on the same medium anaerobically Human and rabbit blood plates made with this medium also gave no hæmolysis and no green zone. When tested on a different nutrient agar (meat infusion plus peptone) with horse blood, all the eleven strains which subsequently proved to be type 12 gave a zone of green coloration, while the two strains belonging to types 11 and 25 give no such zone The strains appeared to be quite different from the so-called "green" strains to which Fry (1933) called attention, since the latter gave typical β hæmolysis in the absence of oxygen and also produced soluble hæmolysin normally in serum broth With our strains no S hæmolysin (Todd 1934) was produced in serum broth, but nine strains (9 of type 12 and 1 of type 25) generated O, or oxygen-labile, hæmolysin.

The fibrinolysin produced in serum broth cultures was feeble—digestion of the clots taking place only after 1 to 3 hours

Fermentation reactions —All the thirteen strains fermented lactose, salicin and trehalose They failed to ferment mannite, sorbite and inulin.

Hydrolysis of sodium hippurate —All strains were negative

Virulence for mice —All strains were of low virulence

While these routine tests were being completed, we recollected that Dr F Griffith had observed the growth of a non-hæmolytic variant from one of his classical type strains * There were also indications in the literature that serological identity did not always go hand in hand with hæmolytic activity on blood plates Thus Todd (1928) had noted the development of non-hæmolytic variants of the Henson strain (type unknown) by passage through mice His variants, however, gave typical hæmolysis in the absence of oxygen Fry's observations (1933) of "green" colony variants have already been mentioned Lancefield (1934), too, described the occurrence of a non-hæmolytic variant of a group B strain after passage through mice, which had the same serological character and virulence as the parent, hæmolytic strain Stableforth (1932) had earlier reported that, among group B strains giving similar serological reactions, the hæmolytic activity was very variable and often absent Recently Coburn and Pauli (1941) have reported experiences with non-hæmolytic variants of a type 12 strain in connexion with an epidemic among infants This will be referred to later In a recent review Lancefield (1941) discussed the relationship between serological identity and hæmolysing activity and concluded that, with regard to group A, "few, if any, frankly non-hæmolytic strains are known"

On testing our thirteen strains by the Lancefield method against stock grouping sera, all gave a typical ring with the A serum and none with B, C or G sera A number of other non-hæmolytic strains isolated from various sources other than the series of cases referred to gave a negative result with all the sera—so that there has seemed to be no reason to doubt the specificity of the group A serum employed. It has been in constant use for many months The results have been checked in two laboratories

Subsequently eleven of the thirteen strains giving a group A reaction were identified as type 12 by the slide agglutination test They also absorbed agglutinin from a type 12 serum The remaining strains were identified by agglutination and absorption tests as type 11 and type 25 respectively

It seems probable, therefore, that eleven of the infections we had been dealing with were in reality due to the type 12 strain Francis had reported, or at least to a variant of that strain which has, for some unknown reason, lost its capacity to produce S hæmolysin. Like the (probable) parent type 12 strains, all our non-hæmolytic strains of this type are insensitive to the sulphonamides

DISCUSSION

The relation of these unexpected findings to those of Coburn and Pauli is not quite clear Their evidence suggested that the respiratory tract infections by their type 12 strain had sometimes originated from certain infants whose throat swabs had not yielded these organisms, but only non-hæmolytic cocci These latter, in two instances at any rate, threw hæmolytic variants on prolonged cultivation in serum broth, and were identified by the precipitin test as type 12 Conversely, typical hæmolytic strains (type 12) isolated from the throats of other infants yielded non-hæmolytic variants on subcultivation, particularly when grown in the serum of infants The majority of our non-hæmolytic strains (ten out of twelve) have not reverted to the hæmolytic variety after many subcultures The two exceptions ("Carter" and "Wilson") threw some hæmolytic colonies after only two subcultures on blood agar, and these bred true The serological reactions of the non-hæmolytic and the hæmolytic variants of "Carter" and "Wilson" were identical

In some respects the observations of Coburn and Pauli differ from our own We have not observed more rapid growth at 22° C than at 37° C. Moreover, our non-hæmolytic variants have agglutinated normally with specific serum, and extracts have given a good precipitin reaction with the group serum ; theirs did not agglutinate with any serum, and gave only a feeble group reaction (precipitin)

A number of important questions arise from these two investigations .—

(1) Are the non-hæmolytic strains really variants of *Streptococcus pyogenes*—or have the serological tests misled us ? The latter seems unlikely, but must be kept in mind

(2) Have we (and other bacteriologists) been frequently missing group A streptococci in our routine cultures because of this loss of the capacity to produce hæmolysis on blood agar ? We do not know but it is possible If it should prove to be the case most of our epidemiological studies will need revision The well-known difficulty of detecting the source of many puerperal and surgical infections might find an explanation in such variations of hæmolysin production

(3) Does this reversion to non hæmolytic variants occur with many of the serological types of group A ? Up to the present it is known to have occurred only with types 11, 12 and 25

(4) What test can we devise for the rapid detection of these non hæmolytic variants of *Strep pyogenes* in routine bacteriology ?

(5) Has exposure of the (presumed) parent type 12, type 11 and type 25 strains to suphanilamide played any part in their reversion to a non-hæmolytic type ? There is at present nothing to suggest such an effect

SUMMARY

Non-hæmolytic streptococci were predominant in swabs from thirteen cases of local infection—seven of them patients with fever or suppuration—clinically resembling that due to the ordinary group A hæmolytic streptococci

All the thirteen strains reacted with group A serum (precipitin test), eleven of them were agglutinated by type 12 serum and also absorbed agglutinin from it The other strains gave a type specific reaction with type 11 and type 25 sera.

The infections with the eleven type 12 strains followed a period in which hæmolytic strains of type 12 had been spreading in the wards Both the hæmolytic and the non-hæmolytic strains were insensitive to sulphanilamide

The mode of spread of these non-hæmolytic strains remains obscure. They were derived from patients in five different wards, one of which was half a mile away from the rest

Our acknowledgments are due to Sir Harold Gillies, Mr J C Cuthbert and their colleagues, in whose wards the cases occurred.

* A non hæmolytic variant of type 1 has since been found among the strains which were in Dr Griffith's possession

She was readmitted three months later for duodenal obstruction with vomiting Glucose saline was given intravenously and by rectum, but the amount vomited continued to exceed the intake She was very dehydrated, and the blood at operation was noticeably concentrated Blood pressure was now 130/90 mm Hg After omnopon, gr ⅓, and scopolamine, gr 1/150, a tracheal catheter with inflatable cuff was passed under anæsthesia from 0 5 g of pentothal, and nitrous oxide and oxygen given A subcostal field block was made with 85 c cm of 1/1000 percaine and a gastroenterostomy performed without incident An inoperable cancer was found around the duodenum, with peritoneal secondary deposits Immediate convalescence was satisfactory, but she died two months later

It seems that the severe jaundice, and possibly the fever, must have been largely responsible for the convulsions during the first operation Personal idiosyncrasy can be excluded by the subsequent history It is possible that local anæsthesia should not be used in such a case, or at any rate that the amount given should be strictly limited

CASE 3

A girl of 25 presented no symptoms She was healthy and active, playing many outdoor games, and was an ambulance driver On medical examination for the WAAF, two enormous abdominal tumours were found—she said her abdomen had always been large One was arising from the pelvis and was obviously ovarian, the other, which also proved to be ovarian, was situated in the upper abdomen Both showed teeth on X ray examination The chest was pushed upwards, the costal angle being about 130° The diaphragm was higher than normal and the lungs came down to the level of the 9th dorsal spine behind The apex-beat was in the third left intercostal space when supine Blood-pressure 130/100 mm Hg, hæmoglobin 76%, red count 4,750,000 Renal function appeared to be normal

Premedication was omnopon, gr ⅓, and scopolamine, gr 1/150, three quarters of an hour beforehand Anæsthesia was induced with 0 25 g of pentothal, followed by nitrous oxide and oxygen A subcostal field block was made with 150 c cm of 1/1000 percaine, and a posterior splanchnic block with 40 c cm of 1% procaine Eight minutes later there were sudden generalised convulsions, violent and continuous, which were controlled in about a minute by 0 15 g of pentothal Artificial respiration was started, with oxygen The blood pressure, taken for the first time, was 60/40 mm Hg After eight minutes the convulsions recurred, being controlled once more in about a minute The blood pressure being unrecordable, ephedrine, gr ¼, was given intravenously Two minutes later the blood pressure had risen to 115/85 mm Hg, and after an uneventful pause of seven minutes the operation began The first stroke of the knife restarted convulsions which were controlled in half a minute and did not recur Again the blood pressure had fallen, to rise spontaneously It seemed that artificial respiration would have to be continued for some time and a soda lime canister was introduced With eventration of the upper cyst there was an immediate improvement, the apex beat dropped 1½ in necessitating the readjustment of a stethoscope diaphragm which was strapped to the chest The blood pressure rose steadily to the preoperative level, but the pulse continued to rise Fifteen minutes later spontaneous breathing started after an interval of 65 min, and the corneal reflex had returned

The upper cyst weighed 26 lb and the lower rather less than half that Her true weight, therefore, was only 7 stone, and the amount of percaine used should not have exceeded 105 c cm In addition to 150 c cm of percaine I had injected 40 c cm of 1% procaine, having a similar toxic effect There was no question of accidental intravenous injection, which is probably ruled out, too, by the time interval Both the procaine and the percaine were analysed and found to be in order Anæsthesia and muscular relaxation were excellent, towards the end of the operation, when largely recovered, the patient objected strongly to manipulations in the pelvis which of course was not anæsthetised

The convulsions were generalised from the start with no warning twitches of the face, and there were no intermissions, yet they were easily controlled by small doses of pentothal In this case as in the others respiratory failure was present from the start, suggesting the advisability of reducing the dose of pentothal to a minimum

That the tumours were causing her considerable physiological embarrassment, in spite of the absence of symptoms, is shown by the well-marked improvement after eventration of the larger cyst Her general condition at the end of the operation was very satisfactory and further restorative measures were cancelled Her colour was always good and she remained warm and her lungs dry

DISCUSSION

In the first and third cases described an overdose of percaine may have been responsible for the convulsions, though it is more than probable that a similarly large dose has been given on previous occasions without any untoward effect The amount should be limited to 15 c cm of the 1/1000 solution per stone body weight, and in its calculation allowance should be made for such factors as the presence of large tumours whose poor blood-supply excludes them from sharing in the rapid absorption of drugs of any sort

In the second case the dose was correct, and was in fact less than that used on a later occasion, but there were the complicating factors of severe jaundice and fever One hesitates to give large amounts of the more toxic anæsthetics, such as ether, to such a patient and would prefer not to deny her the many benefits of local anæsthesia It would, perhaps, be advisable to dilute the percaine to 1/2000, and the dose to half of that calculated by weight This principle should probably be applied to all local anæsthetic agents

It is essential that the convulsions be controlled early, else the patient will certainly die Pentothal should be used even in the presence of circulatory collapse, which cannot adequately be treated until its cause has been neutralised Pentothal, in my view, is preferable to pentobarbital or barbital as their prolonged action is not necessary for the control of the convulsions and will add to the general depression[2] For the same reason the dose must be minimal

Artificial respiration with oxygen will be necessary, and the circulatory depression will respond to intravenous saline, if necessary, adrenaline or ephedrine, again in minimal doses, may be given rather than convulsants such as nikethamide and leptazol

SUMMARY

Within a year, three cases of convulsions, one fatal, were seen after the injection of percaine for abdominal field block Two had received what is now realised to be an excessive amount The other had severe obstructive jaundice and fever

The amount of percaine should be limited to 15 c cm of 1/1000 solution per stone of body-weight, the dose must be reduced for extreme youth or age and for toxæmia, cachexia, jaundice and fever

Convulsions must be controlled immediately by the intravenous injection of minimal quantities of pentothal or hexobarbitone The injection may be repeated if necessary

Artificial respiration with oxygen will be necessary for the respiratory failure which usually follows the convulsions

Circulatory collapse may be countered by intravenous infusion of saline, or by intravenous injection of adrenaline or ephedrine, which antagonise the effect of local anæsthetic agents on the myocardium The use of convulsants, such as nikethamide or leptazol is questionable

My thanks are due to the surgeons, Mr G T Mullally and Mr Stanley Lee, and to Dr Russell Davies for permission to give an account of the first case

SWEET USE FOR SOUR MILK —Dr Austin Priestman writes, for the benefit of those who are not already doing their duty by sour milk "A very pleasant cheese may be made by the use of sour milk which is merely hung up in muslin and allowed to drain for 12–24 hours (overnight is sufficient) The whey is discarded and to the remaining solid material is added a little salt and a little cream"—presumably from the top of the next day's milk "These are stirred and some aniseed or other flavouring added according to taste"

HOSPITAL OR DOMICILIARY CONFINEMENT?

MATHILDA F MENZIES, M D ABERD
ASSISTANT MEDICAL OFFICER OF HEALTH FOR LEYTON

I HAVE analysed antenatal records and breast-feeding figures in Leyton for 1939 and 1940 to bring out some changes effected by the war, and have discussed aspects which, in my opinion, have influenced the trend towards institutional confinement

BIRTHS AND ANTENATAL RECORDS

The distribution of hospital beds for midwifery has been altered by the war In large towns which are evacuation areas fewer hospital beds are available for maternity cases, while a large number have been made available in country or reception areas Leyton is one of the extrametropolitan boroughs included under the LCC evacuation scheme for Greater London In the last ten years an increasing proportion of expectant mothers were being confined in institutions (table I)

TABLE I—REGISTERED BIRTHS IN LEYTON FROM 1931 TO 1940

Registered births	Year—									
	1931	1932	1933	1934	1935	1936	1937	1938	1939	1940
In institutions	546	585	687	630	716	760	767	860	845	692
At home	1266	1081	812	824	777	661	653	649	556	609

This increase occurred in spite of the fact that there is no municipal maternity home in the borough, the bulk of the institutional births were distributed in three hospitals in neighbouring boroughs One of the three, with which the borough council had an agreement for maternity cases dealt with approximately 300 Leyton cases yearly This hospital closed its maternity beds at the beginning of the war, so that the immediate effect on the Leyton midwifery service (except in September, 1939, when there was a temporary evacuation of expectant mothers) was an increase in domiciliary midwifery This continued until September, 1940, and though the actual number of confinements in the borough decreased by about 45% for the last three months of 1940 the proportion of domiciliary to institutional births remained greater than it had been before the war

Of the 692 institutional births for 1940, 202 were of women who had been evacuated, so that of those who were confined in the London area 609 were confined at home and only 490 in hospitals Since 1936 the hospital births had exceeded the domiciliary, by 100 in 1936 and 1937, by 200 in 1938, and by nearly 300 in 1939 But in 1940 the domiciliary births exceeded the hospital births (of the non-evacuated) by over 100 Thus a sudden reversal took place in hospital and domiciliary births, at a time when the home conditions were more overcrowded than they had been for years, in the opinion of the practising midwives

The case-records from the municipal antenatal clinics for 1939 and 1940 are worth comparing, since two-thirds of the 1939 records were completed before the war Only records where the result of the confinement is known have been included Table II shows the number of cases which were entirely normal, and the various abnormalities among the remainder Every case where the blood-pressure was rising and the diastolic reached 90 mm Hg or over has been included as toxæmia, even though no symptoms developed There is not much difference in the figures for the two years The percentage of normal cases is only 3% lower in 1940 (78 7% against 81 4% in 1939) This is perhaps surprising, for there were several months during 1940 when clinics were often interrupted by air-raid warnings, and for a time it was not considered advisable to urge normal multiparæ to attend clinics Besides the possible danger in moving to and fro, there was often delay in getting home, where mothers had usually left children in charge of a neighbour, so the supervision of these normal multiparæ was left to their midwives The 1940 figures are therefore weighted, and indeed it seems likely that even the 1939 figures have a larger proportion of first pregnancies than the average for the borough, since primiparæ made up 45 8% and 48 1% of the numbers in 1939 and 1940 (table III) It is noteworthy that even in a series like this, including a proportion of cases sent to the clinic because they were abnormal, almost 80% of patients had normal pregnancies There was only one death in 729 cases attending over the two years

Before the war the woman herself chose whether she would have her baby in an institution or at home, but if those who had booked a midwife were considered unsuitable for domiciliary confinement it was usually possible to induce them to change their minds The reduction in the number of hospital beds available for maternity cases in London since the war has made it necessary to admit to hospital only those in whom a medical reason for admission is present, or whose accommodation at home is unsuitable for confinement

Comparing the two years, in 1939 approximately 3 primiparæ went to hospital for every 2 who stayed at home, whereas in 1940 1 went to hospital for every 1 who stayed at home Although there were 23 more primiparæ in the 1940 figures there were 2 fewer abnormalities than in 1939, and a larger proportion of the abnormal cases were delivered in hospital in 1940 In second and third pregnancies approximately equal numbers were delivered in hospital and at home in 1939, while in 1940 the proportions were 2 3 in second and 5 7 in third pregnancies Again, the abnormalities were concentrated more in hospital in the 1940 cases, while they were evenly distributed in hospital and at home in the 1939 cases In four and subsequent pregnancies a larger number were confined at home than in hospital in both years, although the proportion was greater in 1940 This is interesting because it is commonly argued that lack of accommodation is an important factor in the increasing preference of mothers for institutional confinement

TABLE II—CASE-RECORDS OF 729 PATIENTS ATTENDING MUNICIPAL ANTENATAL CLINICS IN 1939 AND 1940

—	1939 All cases	1940 All cases
Normal	284	299
Toxæmia	18	13
Instrumental delivery	11	13
Breech	7	8
Stillbirth	5	9
Prematurity	4	9
Prolonged labour	1	6
Occipito post	5	1
Induction	0	3
Cæsarean section	0	3
Other abnormalities	10	10
General diseases	4	5
Total	349	380

TABLE III—NUMBER OF PREGNANCY AND PLACE OF CONFINEMENT IN ALL CASES AND IN ABNORMAL CASES

No of pregnancy	Confinements 1939		Confinements 1940	
	Hospital	Home	Hospital	Home
All cases				
1st	97	63	92	91
2nd	46	42	40	60
3rd	22	25	15	21
4th	8	11	8	21
5th or more	11	24	4	28
Total	184	165	159	221
Abnormal cases				
1st	32	18	34	14
2nd	4	5	12	4
3rd	1	1	5	3
4th	0	3	6	0
5th or more	1	0	1	2
Total	38	27	58	23

Taking the total figures, in 1939 the proportion was approximately 37 in hospital to 33 at home, while in 1940 it was 32 in hospital to 44 at home Of the abnormalities 13 were delivered in hospital to 9 at home in 1939, and 29 in hospital to 11½ at home in 1940 Allowing for the partial selection in the 1940 figures, and for the air-raid conditions between September and December, 1940, it cannot be said that the increased domiciliary midwifery in 1940 increased the proportion of abnormal cases It must be realised too that the home circumstances in 1940 were less suitable for domiciliary confinement than before the war, because families crowded together more, and the room selected for confinement was the smallest rather than the largest, with a correspondingly small window

TABLE IV—DISTRIBUTION OF PRIMIPARÆ AND ABNORMAL CASES IN AGE GROUPS IN 1939 AND 1940

Primiparæ

Age (yr)	Confinements 1939		Confinements 1940	
	Hospital	Home	Hospital	Home
Under 20	22	8	9	9
20–25	41	25	38	37
25–30	23	25	31	33
30–35	8	5	11	10
35–40	3	0	3	2
Abnormal cases				
Under 20	7	1	1	2
20–25	13	18	11	4
25–30	6	7	16	7
30–35	3	2	3	3
35–40	3	0	1	0

I have not worked out for the whole series the percentages in each age-group of those who were confined in hospital in 1939—when the choice was made by the woman herself—but the figures for that year show that in the three age-groups which contain the bulk of the primiparæ (under 20, 20–25 and 25–30 years) the largest proportion went to hospital in the youngest age-group, and the smallest proportion in the oldest age-group (table IV)

TABLE V—COMBINED FIGURES FOR 1939 AND 1940 OF PRIMIPARÆ IN AGE GROUPS

Age (yr)	Confinements	Abnormal cases
Under 20	48	11 (23 %)
20–25	141	36 (25 %)
25–30	112	36 (32 %)
30–35	34	11 (32 %)
35–40	8	4 (50 %)

The percentage of abnormalities (table V) shows a rising figure from the youngest to the oldest age-group It appears therefore that if any medical discrimination is to be made in allocating cases to hospital a larger proportion of the older primiparæ should be admitted to hospital and a smaller proportion of the younger primiparæ This is the reverse of what was happening in Leyton before the war, if it is allowed that the 1939 experience was not exceptional

In the series of cases analysed instrumental-deliveries were seven times more frequent in primiparæ than in multiparæ, and their frequency was related to the age of the primipara occurring once in 48 deliveries in primiparæ under 20 years, and once in 8 deliveries in primiparæ between 35 and 40 Breech deliveries occurred almost entirely in primiparæ, and showed a less definite relation to age Toxæmia was twice as common in primiparæ as in multiparæ and the risk appeared to be nearly as great in the younger age-groups as in the older Stillbirths and prematurity were evenly divided among primiparæ and multiparæ, and showed no definite relation to age Stillbirths are really a mixed group, those which result from difficult labour, and those which are due to disease of the mother or maldevelopment of the fœtus

BREAST-FEEDING

In order to assess more fully the results of midwifery in Leyton in 1939 and 1940, I followed up the breast-feeding of the infants born in these years I asked each health visitor to give me 100 birth cards, chosen at random from a variety of streets in her district I divided the cards into hospital and domiciliary births, and subdivided them according to the number in family and the success or failure of breast-feeding The standard I set for successful breast-feeding was that no complementary feed of milk had been given before the infant was six months old, although I accepted a minority who could not be followed up, where there was evidence that the weight had reached 14 lb while the infant was comple breast-fed The number of records finally dealt with was 357 of the 1939 births, and 309 of the 1940 births Of these, 178 or 49 8% were born in hospital and 148 or 41 4% at home in 1939, and 111 or 35 9% in hospital and 186 or 60% at home in 1940 The remaining small percentage were born in nursing-homes

The health visitor makes her first visit when the baby is 14 days old If an artificial feed is being given by that time, one is justified in assuming that the attendant (midwife or doctor) during the puerperium has not been successful in establishing breast-feeding The heading " Artificial " in table VI contains those cases in which artificial feeding had been started before the baby left hospital, or, in the domiciliary births, before the midwife completed her nursing In 1939, of 178 babies born in hospital, 17 4% were being artificially fed before they left hospital, and 47 5% of the mothers made a success of breast-feeding, of 148 babies born at home, 7 4% were being artificially fed before the midwife left, and 50 7% of the mothers successfully breast-fed their babies In 1940, of 111 babies born in hospital, 21 6% were receiving artificial feeds before they left hospital, and only 40 5% of the mothers breast-fed with success, while of 186 babies born at home, 8 5% were artificially fed before the midwife left, and 50% of the mothers made a success of breast-feeding I consider the percentages very disappointing, but Robinson (1939) found that in 1937 in Liverpool only 29% of babies were on the breast at six months

The most striking difference between the hospital and domiciliary cases is the increase of 10% in the hospital group in the number of babies who were artificially fed within two weeks of birth In 1940 the percentage of babies who were successfully breast-fed was 10% higher in the babies who were born at home than in those who were born in hospital It might be contended that this difference was due to the larger proportion of abnormal cases in the hospital group in 1940, but in 1939 the hospital cases contained only 4% more abnormalities than the domiciliary group, and yet the percentage of babies who were receiving artificial feeds within two weeks of birth was 10% higher in the hospital than in the domiciliary group An inquiry carried out in Birmingham (Cassie 1938) showed that of babies born in institutions 5 8% were artificially fed while the mothers were under the care of the midwives, but of those born on the district only 0 96% were artificially fed

TABLE VI—HOSPITAL AND DOMICILIARY MIDWIFERY IN RELATION TO BREAST AND ARTIFICIAL FEEDING

DISCUSSION

The figures analysed are small but representative of pregnancies occurring in an artisan district of Greater London The increasing hospitalisation of midwifery is not peculiar to Leyton, it is common to most urban areas, and although I do not find that consultant obstetricians recommend that the average normal confinement should take place in a hospital there are medical officers of health and medical officers of municipal clinics who press it. One former medical officer, without producing facts to support his view, recently wrote an article entitled "Domiciliary midwifery—a modern anachronism." It seems likely that this idea, where it exists, has been fostered by the fact that medical officers of health must investigate every maternal death, but may have no contact with normal childbearing. The inevitable result of concentrating on the abnormal, especially where the final result is the death of the mother, is to create an impression in the mind that only by preparing for every eventuality can one hope to achieve successful childbearing. Six official reports on maternal mortality in England, Scotland and Wales have been issued since 1930.

Other medical officers argue that if the woman herself wants institutional confinement, she ought to be allowed to have it. This raises the questions, why has hospitalisation become so popular, has it any disadvantages, and is the mother the best judge of where she should be confined?

Probably the commonest argument advanced by the mother in favour of institutional confinement is lack of adequate accommodation at home. That is the first reason given by Leyton mothers who want to have their confinements in hospital, but the distribution of cases in 1939 and 1940 does not suggest that this is the true reason. Young primiparæ in some cases may be poorly equipped with bed-linen and cooking utensils and some may be unmarried—circumstances which make institutional confinement necessary. The illegitimacy factor does not bulk largely in these figures as only 4 unmarried mothers attended in each year. Some young married couples certainly had homes so poorly equipped that it was essential to recommend hospital for the first confinement, but this was more obvious in 1940 than in 1939. The difference in the distribution of hospital and domiciliary births in the two years (i.e., a smaller proportion of all cases, and especially of young primiparæ, delivered in hospital in 1940) is essentially the result of the mother being advised in 1940 where to have her confinement, instead of, as in 1939, making the choice herself. It would be inaccurate to say that hospital beds were not available in 1940. There were fewer hospital beds, but I had no difficulty in securing admission for every case I recommended either on medical grounds or because of home circumstances. The custom of letting the mother decide whether she should have her confinement in hospital probably arose when hospital confinements were less popular, and the training needs of pupil midwives and medical students resulted in cheap facilities being offered for institutional confinement.

Cost is probably the first thing most mothers consider in deciding. Some evidence of this was supplied by analysing the percentage of Leyton mothers at various incomes who selected hospital confinement in 1938. They were assessed according to the husband's income, allowance being made for rent and for the number of children in the family. It was found that where the fee was totally remitted the number entering hospital represented 10% of all the maternity cases at this scale of income in the borough. Where the husband's income was less than 15*s* per week above the remission figure approximately 25% of the mothers went to hospital, and when the income was between 15*s* and 35*s* above the remission figure approximately 50% chose hospital confinement. If the income was over 35*s* per week above the remission figure, the full fee (then £5 for ten days in hospital) was charged. At this level of income only 15% went to hospital. A hospital charge of £5 is not obviously cheaper than the cost of domiciliary confinement in a district where £2 is the full fee for a midwife with possibly another £2 for a home help, so that this fall in the percentage of admissions at the top of the income scale does not weaken the argument.

The position in Leyton before the Midwives Act, 1936, came into operation was probably not exceptional. At that time women who wanted to have their babies in hospital were assessed according to their means. Women who booked a private midwife were not assisted with the payment by the borough council. The inevitable result was to produce a bias in favour of hospital confinement. If this was happening in other areas no fair estimate can be made of the real demand for institutional confinement as such. The costing returns of the Ministry of Health show that the cost of running a maternity hospital may be as much as £10 per patient per week, and that the average for maternity hospitals in the London area in 1936 was £6 per patient per week. Each case therefore cost about £10, or more if the period in hospital was extended to 14 days.

In Leyton in 1940, 600 cases were dealt with under the domiciliary midwifery scheme, at a cost to the borough of £1700 (this includes £230 which was expended on home helps). This is less than £3 per case. If these 600 cases had been confined in a municipal maternity hospital the cost to the borough would have been greater than the present total expenditure for maternity and child welfare in the borough. To justify such expenditure one would have to be satisfied that the average normal maternity case benefits from being confined in hospital.

The second factor which, in my opinion, has encouraged women to ask for hospital confinement to an increasing extent in the last ten years is fear of pregnancy and of labour. When one remembers the wide and repeated publicity given to figures of maternal mortality one cannot be surprised if the pregnant woman imagines she is running a grave risk by having a baby. "Hospitalisation and the prominence given to the subject of maternal mortality is liable to produce a distorted view in the mind of the pupil."[1] If a distorted view may be produced in the mind of the pupil midwife, how much worse is the effect on the mind of the woman who is going to have the baby. There seems to be some evidence that insistence on the necessity for antenatal supervision may have the unfortunate effect of making women feel there must be something wrong with them instead of engendering confidence in their capacity to bear children normally. Since air-raids developed one finds that women returned from relatively safe areas to danger areas because they could not attend antenatal clinics easily in some of the country areas. The real danger from bombing was a lesser fear to them than the anxiety about their pregnancy or labour. One was inclined to feel impatient with such a reason for return from evacuation. A healthy young woman ought to be full of confidence about her childbearing capacity. "The plain fact that the risk of dying between ages 25 and 60 is smaller for the average married woman than the average single woman in the population, despite the risks attendant upon pregnancy and childbirth, is one which might usefully be stressed as a corrective to exaggerated fears of maternity" (Registrar-General 1935). Hospital confinement certainly surrounds childbearing with an atmosphere of abnormality. Although three out of four women in a ward may have had normal labours, they are in daily and nightly contact with the fourth who may have had a difficult time. By the end of a fortnight there is probably little they do not know of her sufferings. As it is the abnormal which impresses, they can hardly fail to be influenced by what might have happened to them. The more pregnant women are encouraged—by medical men and women, by nurses, by mothers, by husbands, and by the press—to think that their pregnancy is a source of danger to them, the more likely are they to feel they ought to be confined in hospital.

The mother herself is not necessarily in a position to know where it will be best for her to have the baby; she ought to be advised by her doctor or midwife. I have known medical men and women (more often those who have administrative contacts with midwifery rather than clinical experience) argue that hospital confinements should be recommended because they are "safer." Those who hold this view will probably consider that to produce breast-feeding statistics as evidence in favour of domiciliary confinement for the average normal case is beside the point. Is breast-feeding after all of much importance? I think perhaps it may be. The rapid fall in the birth-rate in the last 50 years exercises those who are interested in the future of the race; the decline in breast-feeding may be related to this fall It has been observed that the more highly cultured sections of the community have fewest children, and they tend to have more complicated labours The principles of labour do not differ between the classes, but as Read (1933) has pointed out, the attitude towards it does For the Whitechapel mother, he says, " Trouble, disaster and pain as an accompaniment to the birth of her children is not the picture that is uppermost in her mind To be childless is still a shame amongst the poor—to have a large family is still a joy " The woman who accepts childbearing and looks forward to it has a better chance of breast-feeding and is more likely to have several children than the woman who is full of fears The cultured attitude to labour in spreading downwards through the social classes It may be that increasing hospitalisation of midwifery has effects inimical to childbearing, which are not obvious from studies of maternal mortality

[1] Central Midwives Board. 'Suggestions and instructions regarding the conduct of the course of training of pupil midwives.'

SUMMARY

In Leyton in the last ten years there has been a noticeable decrease in domiciliary births with an increase in institutional births Since 1936 the institutional births have been over 50% of the total births In 1940, for the first time in ten years, the number of domiciliary births is greater than in the preceding year

The case-records from the municipal antenatal clinics for 1939 and 1940, which are weighted with primiparæ in 1940 and with abnormalities in both years, show 81% normality in 1939 and 78% normality in 1940 There is no evidence from these records that the increase in domiciliary midwifery in Leyton in 1940 has coincided with an increase in abnormality

Before September, 1939, the choice of institutional or domiciliary confinement was left to the mother Since September, 1939, the number of beds in London available for maternity cases has been reduced, and institutional confinement of Leyton mothers who were not evacuated has been reserved for those in whom a medical reason for admission is present, or whose accommodation at home is unsuitable for confinement

The 1939 figures show that when the mother made her own choice the youngest primiparæ went to hospital in greatest numbers, with the multiparæ, the larger the family the smaller the proportion of institutional births

The combined abnormalities in primiparæ for 1939 and 1940 show an increasing percentage from the youngest age-groups to the oldest

Analysis of a random sample of birth cards in Leyton, for 1939 and 1940, shows that a larger proportion of babies born in hospitals receive artificial feeds before they are fourteen days old than of babies born at home

The popularity of institutional delivery is probably due primarily to the relatively small charges made for hospital confinement as opposed to domiciliary, and secondarily to fear of pregnancy and labour

The mother herself is too often influenced by prejudice, and her sources of information are incomplete and inaccurate She is not in a position to make a wise decision as to where she should be confined, but should be advised by her doctor or midwife

Institutional delivery is at least three times as expensive as domiciliary midwifery, as practised in an artisan district of Greater London, and unless it can be shown that the normal case benefits from institutional delivery, the charge to the patient ought to bear more relation to the cost to the community

Too great concentration on the abnormal may have led a section of medical opinion to recommend institutional confinements for the normal, who constitute at least 80% of the whole

There is some evidence that insistence on the necessity for antenatal supervision may have developed fears in the pregnant woman A wider view of maternal care might lay greater stress on education of the mental attitude of the pregnant woman towards childbearing

The views expressed in this article are personal, and do not represent the opinion of the borough of Leyton

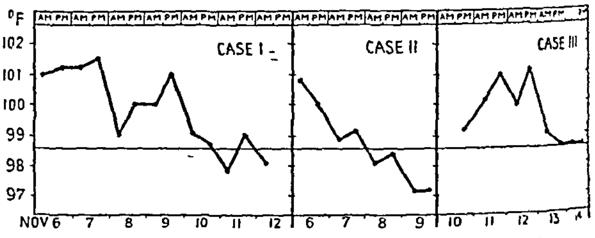
ILLNESS IN SMALLPOX CONTACTS

J C Bowe, M B BELF, D P H
SQUADRON-LEADER R A F
(*From a Royal Air Force Hospital*)

A Royal Naval rating was admitted to a casualty clearing station on Oct 25, 1941, with confluent smallpox which he had contracted in the Persian Gulf He first felt ill on Oct 21, was admitted to the sick bay on Oct 23 and then transferred ashore His condition deteriorated rapidly and he died on the morning of Oct 28

Contacts with the case at the CCS were continuously, 1 medical officer and 2 nursing orderlies, on single occasions, 4 medical officers, one of whom carried out a comprehensive physical examination All contacts were revaccinated on Oct 27–28 and gave typical 24–48 hours immune reaction There were 8 other contacts among embarkation and ambulance staff Of these 15 contacts, 3 men developed febrile illnesses within 8–15 days of contact with the rating The ship had sailed and it has not been possible to ascertain the history of contacts on board

CASE 1—On Nov 6 (12 days after first exposure) the medical officer in charge of the rating developed a febrile illness with severe prostration, headache and backache There was little to find on examination Fauces, cardiovascular system, lungs, abdomen, central nervous system and urine were normal Apart from a secondary anæmia (presumably present for some time) there was no abnormality in the blood-picture Urine and blood cultures proved sterile The temperature dropped to 99° F on the third day when the rash would be expected in variola vera, and there was some amelioration of symptoms His temperature rose to 101° F again on Nov 9 but next morning was normal (fig *a*) and he felt better Lassitude persisted for some time and convalescence was protracted



(*a*) (*b*) (*c*)

CASE 2—On Nov 6 one of the nursing orderlies in charge of the rating complained of headache and backache and was admitted with a temperature of 101° F He was constipated and was given an enema Next morning he was afebrile (fig *b*) and felt and remained fit

Cases 1 and 2 had received 0 75 c cm TAB vaccine on Nov 3 with local and general reactions, and both were fit on Nov 4

CASE 3—On Oct 27 the medical specialist at the RAF hospital visited the CCS and examined the rating He visited the medical officer (case 1) on Nov 8, and on the morning of Nov 10, while returning to hospital, he developed retro orbital headache and that afternoon malaise and headache with a temperature of 99 6° F He was admitted to hospital on Nov 10 and the illness reached its peak on Nov 12 (fig *c*) The fauces were congested and there was a spot of exudate on the right tonsil, but during the previous month he had been having outpatient treatment for a mild chronic pharyngitis which caused only slight discomfort and no general reaction Cardiovascular system, lungs and abdomen normal Blood and urine cultures were sterile and blood picture was normal Lassitude persisted for some time and convalescence was protracted

No illness of the same kind occurred among contacts of these three cases

DISCUSSION

Conybeare[1] reported 7 cases of febrile illness in contacts with smallpox, in only 2 of whom were there skin eruptions He quotes numerous clinical descriptions of smallpox without eruption published by many workers, some of whom maintain that the toxæmia of smallpox is seldom infectious The apparent incubation period in his series was 7 days, while in cases 1 and 2 described here it was 12 days and 14 days in case 3

---

[1] Conybeare, E T *Lancet* 25

It is suggested that the illness was related to contact with smallpox and may have been a modified form of smallpox The MO (case 1) had been successfully vaccinated as a child and all revaccinations (before numerous visits to the United States and in December, 1940) had been unsuccessful He had also been in contact with cases in the USA The sudden onset with fever, headache and backache and amelioration of symptoms with fall of temperature on the third day were suggestive, though the absence of rash and recurrence of fever did not confirm the diagnosis of smallpox The illness was ascribed to the effects of typhoid inoculation, but his good health on Nov 4 and absence of local reaction during the *illness seem to* contradict this diagnosis In case 3 the throat signs were insufficient to account for the severity of the illness, these signs had been present for some time and he had remained fit until the sudden onset on Nov 10 He had been successfully vaccinated as a child and again in January, 1939, with moderate degree of reaction Revaccination on Oct 28 gave no reaction

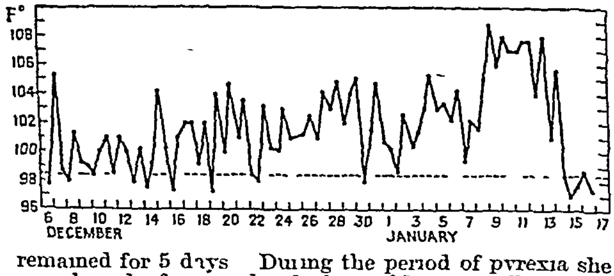
All 3 cases were close contacts—two continuous and the third on a single occasion—so if the illness was smallpox modified by vaccination, close contact with the patient appears to be necessary for infection

I am indebted to Group Captain R S Overton for permission to publish this note and to Squadron Leader R D Bruce for access to his records

HYPERPYREXIA DUE TO HYSTERIA

F P Duras, M D Vienna
HOUSE PHYSICIAN AT THE GENERAL HOSPITAL, NORTHAMPTON

An ATS girl, aged 30, was admitted on Nov 21, 1941, to the ear, nose and throat department with a temperature of 103° F, complaining of pain in both ears, headache, and pains in the lower abdomen There was no discharge from the ears, slight menstrual bleeding per vaginam Two days before admission she had been vaccinated, after which she was stated to have fallen down and knocked her head Both eardrums showed old central perforations but neither middle ear was inflamed, and it was thought that her pyrexia could not be caused by an ear condition Gynæcological examination showed nothing abnormal She was transferred to a medical ward where she developed a swinging septicæmia-like temperature which lasted 6 weeks (see figure) For the first 3 weeks it fluctuated between subnormal and 103°–104° F During the 4th week it was often 105° F and only twice normal Towards the end of the 5th week it reached 108° F where it remained for 5 days During the period of pyrexia she complained of severe headache, giddiness, stiffness and tenderness of the neck, of the whole spine and kidney region She had occasional attacks of shivering



Thorough clinical examination did not reveal anything abnormal X rays of the skull, the whole spine, the chest and an iodoxyl filling of the renal tract were negative Repeated white-cell counts were between 5000 and 6000 with normal differential counts Several blood-cultures were sterile, and two lumbar punctures gave a clear cerebrospinal fluid at normal pressure with normal protein, glucose, chlorides, and cell content, as well as sterile smear and culture Sedimentation-rates of the blood were between 2 and 8 mm an hour Nothing abnormal was found in the urine Agglutination test for typhoid and paratyphoid was negative Treatment which included sulphapyridine, 'Soluseptasine,' *strepto*coccal sera and antipyretics did not have the slightest effect There was no definite sign in support of her complaints She was restless, and at times did not seem clear mentally It was known that she was psychologically unbalanced and emotional, though good-hearted

At this stage it was questioned whether her temperature could be genuine During the 4th and 5th weeks the temperature was taken by a reliable sister who stood beside the patient during the taking Rectal temperatures at the same time corresponded to those taken by mouth In addition there seemed to be no available means by which the thermometer temperature could have been altered Major Ritchie Russell when consulted confirmed the provisional diagnosis of hysteria and when taken by him the temperature was *normal for the first time in a fortnight*

The patient confessed that she experienced a severe psychological trauma when 10 years old Whenever she thought of it, and while in hospital it was almost perpetually on her mind, she got very hot and perspired Since this confession the temperature has remained normal She was persuaded to try to produce the temperature again while concentrating *on the quoted* experience Unfortunately this stimulus did not act, and the temperature remained *normal* She was discharged on Jan 26, 1942, happy and with no complaints and went back to the ATS, but she has since been admitted to hospital as a fully-developed case of hysteria

* * *

There seems to be no doubt about the existence of hysterical fever, and apparently authentic cases have been observed with continued or intermittent pyrexia with sudden jumps to 108° F and even 113° F The absence of the corresponding accessory symptoms is characteristic An excellent survey of hyperthermia, genuine and spurious, has been made by MacNeal[1]

DEATH FROM PHENOTHIAZINE POISONING

D R Humphreys, M B Birm, M R C P
RESIDENT MEDICAL OFFICER AT QUEEN ELIZABETH HOSPITAL, BIRMINGHAM

A SCHOOLGIRL of 6 years was admitted to hospital on Dec 23, 1941, because of pallor and vomiting She had been well until Dec 7, when she complained of rectal irritation, and her doctor was consulted six days later and diagnosed threadworm infestation Phenothiazine was prescribed in a dose of 2 grammes daily On Dec 13 the girl took 1 5 g and on the 14th and 15th 2 g each day The mother noticed a few black threads in the stools, but it was difficult to decide later from her description whether they were stained threadworms or not On the 16th the child looked rather pale, but had 2 g again On the 17th she was tired and looked a *little* yellow, and she was given only 1 g on this and the next day—a total of 9 5 g over a period of six days On the 20th she looked ill and began to vomit, and was kept in bed until her admission to hospital three days later

On admission she was pale and ill-looking with a very slightly icteric colour Her temperature was 102 4° F, *pulse rate* 130 and respiration rate 25 per min The spleen and liver were not palpable, there were no hæmorrhages, and nothing else abnormal was found on examination Blood-count on admission was as follows

Red cells, 1,250,000 per c mm
Hæmoglobin 26%
Colour index, 1 04
White cells, 16,800 per c mm

Polymorphs, 71%
Lymphocytes, 24%
Monocytes 3 7%
Metamyelocytes, 0 3%

In a differential count of 300 white cells 35 normoblasts were seen
Reticulocytes 22 6% Platelets, 236 000 per c mm

On Dec 24, 300 c cm of blood was given by drip over a period of 3 hours Half an hour after conclusion of the transfusion she had a rigor Temperature rose to 106 8° F and the *pulse rate* to 164 per min She was given fluids and alkalis in large doses, but became worse, incontinent and gradually *comatose* She died about 11 hours after the transfusion No threadworms were passed during her period in hospital

Autopsy was performed by Prof Haswell Wilson 36 hours after death The body was of average development and fairly well nourished It was anæmic in appearance with a just perceptible trace of jaundice of the skin and conjunctivæ

---

[1] MacNeal, W J *Arch intern Med* 1939, 64 806

The pericardial sac was normal There was soft jelly-like antemortem clot in the right side of the heart The right ventricle was dilated There was no lesion in the valves, and the muscle was pale from extreme anæmia The lungs were free from adhesions Both were poorly aerated and slightly œdematous at the bases, and were pale from anæmia There was no evidence of bronchitis or pneumonia The peritoneum was normal The liver was pale from anæmia, there was no visible fat, and nothing in the gross appearance to suggest toxic hepatitis The spleen was dark red and firm The kidneys were pale, and there was nothing to suggest nephritis The alimentary tract showed no evidence of inflammation or other abnormality, and no threadworms were seen The brain and its membranes were anæmic in appearance, but there were multiple small hæmorrhages in the region of the corpus callosum The rib marrow was fluid and dark, and the femur marrow was abundant and dark red Section of liver showed no evidence of toxic hepatitis

The blood-picture, and the contrast between the dark red spleen and marrow and the pallor of the other organs is characteristic of an acute hæmolytic process It is interesting that the hæmolysis, which evidently began on the third day of phenothiazine administration, should progress so alarmingly several days after administration had ceased

Anæmia following phenothiazine medication was recorded first by de Eds, Stockton and Thomas,[1] and was of hæmolytic type with high reticulocytosis Hubble[2] recorded three cases of anæmia, in one of which the count fell to 2,900,000 per c mm with 10% reticulocytes, but in which jaundice was a well-marked feature, and he suggested that hepatitis was the chief toxic effect In the case here recorded jaundice was barely perceptible, and the liver was practically unaffected

I wish to thank Prof K D Wilkinson for permission to publish this case, and Prof Haswell Wilson for the report on the autopsy and sections

---

Reviews of Books

Radiology Physics

John Kellock Robertson, F R S C , professor of physics, Queen's University, Kingston, Canada London Chapman and Hall Pp 270 18*s*

Professor Robertson's book is described as an introductory course for medical or pre-medical students and for all radiologists It is a clear and accurate exposition of the technical and physical considerations lying at the basis of modern radiation therapy and diagnosis, containing chapters on alternating currents, the production of high voltage, the measurement and control of high tension voltage, cathode rays, positive rays and isotopes, roentgen-ray tubes, valve rectification, general properties of X rays, secondary X rays and absorption, roentgen-ray dosage, radioactivity, supervoltage tubes and high speed particles, artificial radioactivity and high-frequency currents The outlook is modern and the information up to date, for example, the section on radioactivity deals clearly with artificial transmutation, and descriptions of supervoltage equipment and of the cyclotron make an excellent introduction to the study of artificial radioactivity The emphasis, unlike that of many books on radiology, is such that the diagnostic radiologist will find much to interest him as well as the man whose main interest is therapy The book, well produced and illustrated as it is should serve well both students reading for the diploma and radiologists who wish to know more of the scientific basis of their craft

Immunity against Animal Parasites

James T Culbertson, assistant professor of bacteriology, College of Physicians and Surgeons, Columbia University, New York London Humphrey Milford, Oxford University Press Pp 274 36*s* 6*d*

In 1929 W H Taliaferro, in "The Immunology of Parasitic Infections," gave an authoritative account of the knowledge then available on the subject Professor Culbertson begins where Taliaferro left off and brings the subject up to date Work published before 1929 was cited fully by Taliaferro, that published later is equally fully listed in the present work, and for this alone the book would be valuable It deals consecutively with natural resistance to parasitic infections, age resistance, acquired immunity, immune responses and the mechanism of immunity Immunity following specific infections is discussed in relation to the amœbic infections, leishmaniases, trypanosomiases, malarial infections and coccidioses, and infestations with cestodes, trematodes, nematodes and some arthropods Finally it deals with various groups of parasites from the point of view of immunity resultant on infection and vaccination, and the production of characteristic immune responses of possible value in diagnosis The book is a valuable compendium of information for workers on parasitic immunology

A History of Science

(3rd ed) Sir William Cecil Dampier London Cambridge University Press Pp 574 25*s*

Thirteen years ago Sir William Dampier wrote, in comparatively short compass, a history of the evolution of science His book was enthusiastically received, and a second edition is now followed, after some ten years interval, by a third The history of science has been studied much of late, and the stream which formerly seemed to be disturbed and often interrupted now appears as a broad and continuous river Sir William has embodied much of this new knowledge in his work, and has outlined the wide prospects which now lie in view of the scientific inquirer Indeed, in his endeavour not to omit the smallest point worthy of notice, he has somewhat overburdened his main theme , but this does not detract from the review which he gives of the outstanding achievements of science, or his comprehensive vision of the essential unity of different aspects of man's study of the phenomena of nature He has emphasised that there is no real antagonism between science, metaphysic, and religion that philosophy, and not pure materialism, is essential for the continued progress of natural science "At such historic moments" he says of the great achievements of the masters "physical science seems supreme But the clear insight into its meaning which is given by modern scientific philosophy shows that by its inherent nature and fundamental definitions it is but an abstraction, and that with all its great and ever-growing power it can never represent the whole of existence Science may transcend its own natural sphere but to see life steadily and see it whole we need not only science but ethics, art and philosophy we need the apprehension of a sacred mystery, the sense of communion with a Divine Power, that constitute the ultimate basis of religion "

The Intervertebral Disc

F Keith Bradford, M D , and R Glen Spurling, M D London Baillière, Tindall and Cox Pp 158 22*s*

This book deals chiefly with the part played by the intervertebral disc in causing back pain and sciatica It is the first clinical monograph on the subject to appear in this country, and the authors have succeeded in condensing their own experience and a review of the rather voluminous published work into a slim and handy volume There are lucid chapters on the anatomy, physiology and pathology of the intervertebral discs, and the clinical picture is clearly drawn The indications for conservative treatment and operation are discussed , a useful series of representative case-reports will make many readers feel that this is a commoner lesion than they had supposed

Manual de Psicoterapia

Emilio Mira y Lopez, formerly professor of psychiatry in Barcelona University Buenos Aires Aniceto Lopez Pp 314

This comprehensive and readable treatise was prepared because Professor Mira believed it high time that psychotherapy should form part of the instruction of medical students in Latin America , there were already Spanish translations of standard works on the subject, propounding a particular doctrine or method, but no survey of the whole field He therefore amplified a series of lectures he had delivered in 1941, and hoped the book would serve to prevent the development of sectarian groups of psychotherapists in South America His presentation is broad and fair enough to succeed in this aim so far as a book can further it It is wider in its scope than any comparable F [illegible] ork

THE LANCET

LONDON SATURDAY, JULY 11, 1942

EFFECT OF WAR-TIME FOOD ON CHILDREN

It should be possible to judge the adequacy of our children's diet by studying the state of their health, but there is as yet little information about child health during the war [1] and many changes besides diet may have influenced it, moreover, it is usually impossible from a purely clinical examination of an individual child definitely to correlate subnormal health with specific dietetic deficiencies unless they are gross The main effects of the war on diet have been a higher carbohydrate intake for civilians as a whole, including school-children, as a result of shortage of meat, fish, eggs, milk and fruit, a better diet for the poorest families, since there is now no mass unemployment and more money in the pockets of the poor (for poverty is the greatest cause of dietetic deficiencies in peace-time), and a fairer distribution of foodstuffs through rationing, the national milk scheme, and school and other communal meals, though these facilities still need extending The net result has been a levelling down of the diet of the majority of civilians towards that of the poor, and a levelling up of the diet of the poorest The inadequacy of the prewar diets of the poor scarcely needs stressing, but recent work in Toronto,[2] showing the remarkable effect on mothers and infants of supplementary feeding of expectant mothers, and the findings of the People's League of Health Survey published in these columns last week (p 10) emphasise the point once more, the poor Toronto diets resemble in many ways the present diet of most of us in Britain

The experience of Germany during and after the last war, when food shortage was acute, was that the growth of children was retarded, and the death-rate from tuberculosis rose rapidly and steadily [3] On the other hand, infant mortality declined in spite of severe food privation for the people as a whole, and, apart from the influenza pandemic, deaths from the common infectious fevers of childhood showed no tendency to rise Vitamin-deficiency diseases—rickets, scurvy, keratomalacia, and so on—increased These findings suggest subjects for review in this country where few observations on the growth of children under present-day war conditions have been published This spring MILLIGAN, with the help of LEWIS-FANNING of the statistical department of the Medical Research Council,[4] compared the growth of two groups of Glossop school-boys, observed in 1940–41 and in 1941, with similar groups observed between 1936 and 1939 Both war-time groups showed a significant reduction in rate of weight increase, the weekly rise in weight of the group observed in 1941, during the period of strict rationing, was less than half that of the prewar controls Glossop had been free from bombing and there seems no doubt that it was inadequate diet which retarded the boys' growth, though the actual deficiencies responsible are uncertain Yet the prewar heights and weights of Glossop boys were certainly far from optimal, and in 1938 Glossop boys aged 13 years were nearly a stone lighter than boys at this age at Christ's Hospital But BASHFORD [5] has found London 14-year-olds in 1941 at least as heavy as in 1938 Many more observations on rate of weight increase are urgently required, particularly on boys and girls over 14 years, who are particularly likely to be hard hit by rationing STOCKS [6] has reviewed the vital statistics of England and Wales in the second year of war Infant mortality (excluding air-raid casualties) rose on the average by 6½ per 1000 live births in the second four quarters of the war, compared with the four quarters immediately preceding the war, the first quarter of 1942 however promised better The efficacy of the sulphonamide drugs in many of the serious infections of infancy should have produced, but for adverse war influences, a definite drop in infant mortality comparable to the recent drop in maternal mortality. Important among these adverse effects are probably a diminished supply of breast milk—a subject on which information is now being collected—and an increase in anæmia among infants Recent death-rates from the four common infectious fevers—diphtheria, whooping-cough, measles and scarlet fever—have fluctuated, but 1941 was a bad year for the first three of them Deaths from tuberculosis show a disquieting rise for example, among children under 10 years in 1941 deaths from all forms of tuberculosis were 45% in excess of those in 1939, among children under 5 years old death from tuberculosis of the respiratory tract had nearly doubled This increase, which may well have been exceeded during the past six months, is due to a variety of factors, including the use of unboiled milk in country districts, but it seems likely that reduced resistance from dietetic deficiencies also played an important part

A survey reported on p 32 has demonstrated a drop, as compared with prewar groups, in the average hæmoglobin levels of school-children and has shown a very high incidence of anæmia among children under 2 years, particularly in day and residential nurseries Anæmia at preschool ages could and should be successfully tackled by iron administration Whether anæmia at school age is widespread in all parts of this country, whether or not it is a conditioned deficiency and its response to iron treatment have all yet to be determined WIDDOWSON and MCCANCE's work [7] indicates that the use of wheatmeal instead of white bread will not increase the iron available for hæmoglobin building and may even diminish it In Germany it appears that large-scale administration of vitamin C to school-children has improved growth and resistance in infection [8] Whether vitamin-C deficiency has retarded the growth of British children is not known, but the intake is almost certainly below the optimal [9] The wide use of ascorbic acid for infants before the Government issue of fruit juice may well have saved us a crop of infantile scurvy No figures apparently exist concerning the incidence of rickets last winter, but both doctors and mothers have doubted the adequacy of the official dosage of "cod liver oil compound" for children under 6 months, and many infant welfare medical officers have supplemented the dose There need be no shortage of vitamin D, and it is to be hoped that the official prophylactic dose for the first year of life will be increased before next winter

[9] Harris, L J *Lancet*, 1942, i, 642

The diet of children today is probably better than last winter as a result of better distribution of milk, more school meals, and the system of priorities in eggs and oranges It is useless to hope for an optimum diet in war-time, but further improvements should be possible for children Some subjects still needing consideration by those controlling food policy are additional provision for adolescents for whom neither school milk nor school meals are available, provision of adequate vitamin C for children from school age onwards, of adequate vitamin D for babies under 6 months, and of iron for infants and preschool children When minerals or vitamins can be supplied in sufficient quantity in natural foodstuffs these should be utilised, but preconceived ideas of what is natural should not stand in the way of the full use of laboratory products when necessary Compared with millions on the continent of Europe children in Great Britain are excellently fed, but that should not blind us to defects in their diet or to the need for constant vigilance to remedy every defect we can The Ministry of Food has earned merited praise as a business organisation, but only history will show whether it has made wise use of this great opportunity to preserve and promote the health of our people

TOTAL VERSUS SUBTOTAL HYSTERECTOMY

Once more the challenge has been flung down by the totalitarians, championed this time by no less a transatlantic authority than Counseller, and no doubt the moderates will rally to the call If a hysterectomy is to be performed for some benign pathological condition, should it be subtotal or total ? McKinnon and Counseller[1] have tried to assess the relative advantages and disadvantages of the two procedures from the case-records of 2684 hysterectomies performed at the Mayo Clinic between 1935 and 1939 This is a formidable array of material, large enough to reduce the statistical error to a minimum Being the work of expert surgeons under ideal conditions it has an added uniformity which lends force to any conclusions drawn Of these hysterectomies, 1920 included the cervix, 764 did not To eliminate the incidental physical hazards of individual cases the whole series was subdivided into two grades—good and bad operative risks—so that in the group of good surgical material the type of operation was the only known variable In this class were segregated 1497 patients, of which 1034 underwent total and 463 subtotal hysterectomy

The arguments that favour the total operation can be epitomised as follows The cervix is eliminated as a possible source of subsequent malignant change This risk has been computed at 2% to 8% by various authors,[2] and it is a particularly real one if the cervix is already diseased by erosion and infection at the time of operation In such a cervix subsequent cauterisation is neither an efficient nor a method of eliminating the risks of carcinoma moderate point of view has always refused to that an organ, merely because it is a candidate f malignant change, should be ablated as a sort long-term insurance , but where an organ is already known to be predisposed to malignant change by chronic inflammatory disease it is reasonable to extend the scope of operation to include that danger zone, i it can be done without subjecting the patient to a mischievous risk Most surgeons now agree that all cervices that are in any way pathological should be removed with the body of the uterus if the condition of the latter is the primary indication for operation. The next argument in favour of the total operation i that the cervix as a focus of infection is removed. Certain forms of urinary infection, notably trigonitis and certain types of cystitis, have their origin in an infected cervix , the cervix is also sometimes the primary focus in certain classes of iritis Apart from these considerations, it is a painful disappointment for a woman, having undergone subtotal hysterectomy, to be left with a persistent leucorrhœa that may only be cured ultimately by the vaginal removal of the cervical stump Occasionally these stumps bleed slightly under hormonal influence if a portion endometrium is retained above the cervix, and vascular erosions also cause inconvenience and worry to the patient and her doctor by reason of a bloodstained discharge That the total operation provides a more stable vaginal vault is anatomically evident After a subtotal hysterectomy the cervix is left suspended only by such parts of Mackenrodt's ligament as the surgeon has seen fit to leave and it is liable on rare occasions to prolapse After the total operation the vaginal vault can be united by sewing both cervical ligaments together in the centre This technique minimises the risk of vault prolapse considerably In McKinnon and Counseller's series, after the total operation there was only one case of vault prolapse , after subtotal operations 23 had to have a subsequent plastic operation for this complication in the same five-year period Pulmonary complications, such as embolus, were commoner after subtotal than total hysterectomy, which McKinnon and Counseller attribute to infection of the stagnant blood vessels in the broad ligament The last point—and one not generally accepted in this country—is that in the Mayo Clinic series the mortality was lower for the total operation, being 0 78% for the total and 1 04% for the subtotal operation in the whole series, and in the cases of least surgical risk 0 18% for the total and 0 86% for the subtotal operation

In favour of subtotal hysterectomy it can be said that it is followed by a smoother convalescence with less reaction such as postoperative fever and there i less chance of urinary infection After the tota operation, in which the bladder has been traumatise by dissection from the anterior aspect of the cervix functional retention of urine is a commoner complication This in itself predisposes to urinary infection which in turn is aggravated by the number of catheterisations that may be necessary Secondary hæmorrhage from the cut edges of the vaginal vault and th descending branches of the uterine artery is anothe complication of total hysterectomy, and in 8 of th 1920 total hysterectomies in this [illegible] his complica

2 Black, M F *Ibid*, 1939, 68, 898

tion needed treatment Finally for all infected cases the subtotal operation carries a smaller risk of peritonitis supervening The conclusions that McKINNON and COUNSELLER arrive at are these The elimination of the cervix as a source of subsequent trouble and the lower immediate mortality-rate of the total operation far outweigh the risks of any complication that may arise after total hysterectomy Except in cases already infected at the time of operation total hysterectomy is the operation of choice where a surgeon is called on to remove the body of the uterus for benign conditions The increased risk of secondary hæmorrhage from the vaginal vault, and the increased risk of urinary complications following total hysterectomy, can be minimised by operative technique and a careful postoperative regime The fact that the Mayo Clinic is performing 2½ times as many total operations as subtotal indicates the trend of modern American thought

CHEMOTHERAPY IN BIOCHEMICAL TERMS

THEORIES of sulphonamide action have exhibited the familiar biological process of recapitulation and advance The questions which have been asked of most chemotherapeutic drugs during the past fifty years have now been answered with certainty for these new ones—sulphanilamide does act directly on the parasite and not, for example, by stimulating the defences of the host, it does act itself, and not by conversion to more active compounds[1] But hitherto it has been difficult to describe the mode of action of the sulphonamides in greater detail Localisation of their action in particular parts of a parasite, or description of their effects in terms of specific pharmacoynamic action, have not been of much practical use r fruitful in the production of new drugs Correlaion of action with chemical or physical properties ias been satisfactory in limited fields only There vas a gap in our knowledge other unknown factors vere more important in conditioning drug activity Che receptor theory as originally propounded connected drug action with vital processess of the cell, such as respiration These connexions were forgotten One of the contributions made to medicine by sulphanilamide has been in stimulating the biochemist's interest in drug action when he had become preoccupied with enzyme chemistry and nutrition It seems obvious now that the primary action of chemotherapeutic substances must be biochemical, this science has long been concerned with the action of inhibitors on living processes- Yet chemotherapy has been behind pharmacology in receiving biochemical interpretation The explanation of eserine activity as due to inhibition of choline esterase came 14 years before the description of sulphanilamide action in terms of competitive inhibition of enzymes acting on p aminobenzoic acid This may be because more pharmacologists than chemists are taught biochemistry, or because sulphanilamide, an eminently suitable subject, has only recently been available

The simplicity of the structural relation between sulphanilamide and *p*-aminobenzoic acid has attracted much attention, but the picture is not complete without further refinements, which again can be given satisfactorily only in biochemical terms Sulphanilamide inhibition depends primarily on limiting the organism's use of *p*-aminobenzoic acid, the inhibition of yeasts,[2] of the dermatophyte *Trichophyton purpureum*[3] as well as of the earlier investigated bacteria can be removed by *p*-aminobenzoic acid These findings are from nutritional experiments, and it has been important to demonstrate that the anti-sulphanilamide effect of *p*-aminobenzoic acid is a specific one, and not a general growth-stimulation, this point has recently been confirmed[1,4] The anti-sulphanilamide activity of *p*-aminobenzoic acid is however also shown by other, structurally unrelated, compounds,[5] notably, in the case of *Bacterium coli*, by methionine and certain purines The effects of these compounds are not so general as that of *p*-aminobenzoic acid, and they are pictured by KOHN and HARRIS as being biochemically related to *p*-aminobenzoic acid, for example, the acid may be necessary for the formation of the compounds, while they are necessary for growth of the organism The existence of anti-sulphanilamide compounds explains how media may be obtained in which the action of sulphanilamide is less than it is in vivo the medium has only to contain the greater amount of antagonistic materials Such inability to reproduce in vitro the in-vivo action of sulphanilamide once led to the incorrect belief that its action must be indirect, for example on the toxins of the invading organism. The recent restatement in Switzerland[6] of this rejected theory is only evidence of the present isolation of scientific work.

BONE MECHANICS

SINCE the pioneer researches of Meyer, Wolff and Culmann, the essential features of bone mechanics have become textbook knowledge In brief, a bone is built as an engineer would build it if he had sufficient finesse The thickness of a long bone down its length is, for example, proportional to its "bending moments", and internally its trabecular structure (like the Forth Bridge or the Cologne spires) offers a faithful picture of the stresses and strains to which it is subjected Moreover bone can readjust its "stress diagram" when for surgical or other reasons the forces acting on it are changed How does all this come about? The fundamental fact underlying the response of bone to tension and compression is that osteoblasts, like other fibroblasts,[7] can orientate themselves under stress—a fact which has been described as the "physiological foundation of bone surgery"[8] Glucksmann[9] has now studied the effect of mechanical stresses on skeletal tissue in vitro, and he finds that its response is a direct one, the complicating effects of muscle, nerve and arterial supply are wholly eliminated Furthermore, tension stresses stimulate bone formation—a fact which the orthopædic surgeon has already placed on a firm though empirical footing Glucksmann's research rounds off a long history of the study of bone mechanics on a physiological level The need now is for an extension of the elementary physiology of stress to the surgery of nerve and skin In the case of nerves a promising beginning has already been made[8]

Annotations

CLINICAL PATHOLOGY OUTSIDE LONDON

THAT the Ministry of Health is fully alive to the importance of pathology in the Emergency Medical Service is indicated by the appearance of circular 2658, dated June 19, which sets out the plans of the ministry *in regard to hospital* or "*clinical*" *pathology in the* provinces This work has up to now been done in a variety of laboratories of which the principal have been those of the voluntary hospitals Facilities vary greatly from area to area but few places have been out of the reach of a service of some sort Although not satisfactory the state of affairs has apparently not so far been judged urgent enough to call for the vigorous measures which in the autumn of 1939 led to the establishment under the Emergency Public Health Laboratory Service of fully equipped and staffed laboratories throughout the country This was an emergency measure and subsequent modification was inevitable In the case of clinical pathology it has fortunately proved possible to move more gradually This branch of pathology was first dealt with in the London area by organising the EMS hospital pathological service on the sector basis each centring on a great teaching hospital It is now proposed to do something of the same sort outside London The ministry will recognise certain laboratories throughout the provinces as "area" laboratories, it is implied that they will be attached to hospitals These area laboratories will do the work for the hospitals in which they are situated and also for other hospitals in their area, they will also undertake work for practitioners In smaller hospitals there will be "side room laboratories," not under the immediate and continuous supervision of a medically qualified pathologist The ministry will assist in the provision of staff, equipment and even in exceptional cases of buildings, appointments of medical staff will be made in consultation with the authorities of the hospital concerned In return the area laboratories will undertake without further payment work for patients for whom the EMS accepts financial responsibility For work coming from other hospitals the area laboratory will charge 3s per specimen, fees for work done for practitioners will be charged on a schedule based on that of the BMA The fees for all this outside work will be credited to the ministry This is likely to raise some argument in the case of laboratories whose pathologists have been receiving a proportion of these fees as a part of their emolument, but an acceptable adjustment should not prove impossible The grouping of laboratories will be arranged by the hospital officer in consultation with the honorary consultant in pathology where one is appointed This consultant officer, it is suggested, shall be a member of the staff of a university pathological department Considering that the clinical pathological service of many provincial non teaching hospitals has been developed and integrated with the clinical service to a degree at least as high as in the university hospitals this condition of appointment seems somewhat invidious On the whole the circular represents a definite step towards a national service in clinical pathology, and it is good to see that, in line with the recommendations of the BMA Medical Planning Commission and the Nuffield Trust for Provincial Hospitals, it recognises by implication that clinical pathology must be practised in laboratories attached to the hospitals Some of its recommendations will raise issues with established interests both in the voluntary hospitals and among clinical pathologists outside them, but fortunately the policy is sufficiently wide to permit of variations to suit local circumstances The circular makes no mention of the need for a pathological service within the National Health Insurance system, but the establishment of area laboratories will help to make strait the way for this essential step the time comes to take it

A NEW VIRUS DISEASE

THE number of new viruses discovered in human and animal diseases grows steadily and Paul Durand[1] added to the list one isolated from himself in Tunis 1939 The symptoms of his illness were in no *specific or remarkable, consisting chiefly of* anorexia, constipation and insomnia, and a temperature of 100 6° to 103 8° F lasting 11 days The blood picture was not abnormal and blood cultures were sterile Agglutination tests with typhoid and paratyphoid organisms were negative, as was the Weil Felix reaction Venous blood taken on the second day of fever caused a febrile reaction when inoculated into guineapigs and the virus has been maintained by passage of infected guineapig spleen Practically the same symptoms appeared in two people inoculated with infected guineapig spleen and in the case of a laboratory infection described by Findlay[2] In one of the men inoculated with infected guineapig spleen the virus was found in the blood from the 4th to 21st days, in the urine from the 5th to 17th days, and in one sample of cerebrospinal fluid taken on the 6th day The rhesus monkey, dog, Syrian hamster, merion, white rat and mouse are all susceptible to a varying degree when inoculated by the intradermal, intranasal and intracerebral routes Findlay, using the original strain of virus, has shown that the virus grows in suspended cell cultures of chick embryo tissue and tyrode solution and in the developing chick embryo Durand has found it to have remarkable resistance to various chemical agents It is unaffected by the action of bile for 213 days at 4° C, and is reduced in virulence but not inactivated by contact for 18 hours with 1% phenol or formol The virus remained active at least 213 days at 4° C and when preserved in 50% glycerin in saline was active after 18 hours at 37° C Filtration through gradocol membranes indicated its size to be between 38 and 52 mμ The virus has not been found to be related immunologically to any of the present known viruses, though Durand emphasises the similarity of it behaviour in animals to that of lymphocytic choriomeningitis Whether this virus occurs in areas other than Tunis is a question that will probably have to be postponed for a few years now, till more is known about it, it seems fitting that the virus should be called after its discoverer

INORGANIC AND ORGANIC IRON

Bunge probably thought he had settled the question for all time when in 1885 he made the pronouncement that iron in organic combination was of more value in nutrition than its inorganic salts He must have known of course, that inorganic iron had been a therapeutic mainstay for years, for Blaud had introduced his famou pill in 1831,[3] but Bunge[4] considered that his own result justified the change of opinion In 1933, the subject was again explored by Elvehjem and two of his collaborators[5] They measured chemically the inorganic iron in a number of foodstuffs, and compared it in two instances with the quantities of iron in the same foods which were available for hæmoglobin regeneration anæmic rats They concluded that the inorganic i and the available iron were one and the same, and substantiated this by showing that the iron organically combined in hæmatin and similar substances was of no use to the growing rat The introduction of the idea that only the inorganic iron in foodstuffs was available, and that this availability could be measured by ch

thods, stimulated a deal of work at Wisconsin and ewhere which was not very concordant or satisfactory. vertheless, the basic generalisation was accepted by st people as a working hypothesis.[6] Just as opinion s showing signs of settling down, Oldham, Schultz d Morse[7] reported very careful work on a single baby uch went to show that the hæmoglobin iron in meat s as useful to the child as inorganic iron but that the n in a wheat-germ preparation, although undoubtedly organic, was much less readily absorbed. Oldham,[8] oreover, went on to show that the organic iron in cooked meat was as truly unavailable to rats as it d always been thought to be, but that some change ok place when it was heated which allowed the animal make use of it. These later findings explained how her investigators had come to consider hæmoglobin d hæmatin iron unavailable, but Oldham's results readeagled all the work which had been done on the sumption that only inorganic iron was likely to be ailable in human nutrition, and two papers have ppeared in the last few weeks which have again conunded the whole issue. Widdowson and McCance[9] ave shown that there may be something in brown bread hich prevents the absorption of dietary iron and have ggested that the interfering substance may be phytic cid. Furthermore, Black and Powell[10] have demontrated that even uncooked and untreated hæmoglobin on may be absorbed and utilised by normal and næmic persons. Their subjects were given a litre of lood by duodenal tube and absorbed 10–25% of the on so administered. This piece of work would have een still more valuable if the same patients could have een given an equal quantity of inorganic iron, and the mounts absorbed compared; this remains to be done. here can be no doubt today that inorganic iron is bsorbed when given in therapeutic doses. Some time n the tomorrows investigators will clarify the position bout iron in food and show us wherein lies the truth. leanwhile, for purposes of practical, everyday British-Restaurant nutrition it looks as though we must go ack to the good old days when the iron in a diet neant the total iron in it, and all one could do was to neasure it and base one's assumptions of intakes and equirements on that figure.

PREGNANCY AND DIABETES

BEFORE the discovery of insulin pregnancy in a diabetic woman was a rare occurrence and highly dangerous to mother and child. Insulin has reduced the maternal fatality in diabetics from 30–40% to about 2%, but the fœtal fatality still remains in the neighbourhood of 40%. Three factors must be borne in mind when pregnancy for a diabetic mother is considered: effect on the mother; chances of obtaining a live child; and possible inheritance of the disorder. Lawrence and Oakley[11] and Fouracre Barns[12] believe there is no sufficient evidence that pregnancy increases the ultimate severity of the diabetes. Most diabetics require a slightly increased insulin dosage during pregnancy especially during the last third, and the control of the disease is made more difficult by the lowered renal threshold for glucose and consequent wastage of carbohydrates and increased chance of ketosis. In 25 diabetic pregnancies observed at University College Hospital Barns found an incidence for toxæmia of late pregnancy of 46% and for pre-eclamptic toxæmia of 29%, compared with an incidence in 1864 consecutive non-diabetic pregnancies of 36% for toxæmia of late pregnancy and 27% for pre-eclamptic toxæmia. His high incidence is accounted for by the inclusion in the toxæmic group of any woman with a BP over 130/70 mm Hg. Priscilla White and her collaborators in Boston, whom he quotes, found eclampsia to be 50 times as common in diabetics as in normal pregnant women. Lawrence and Oakley stress the difficulty of diagnosing toxæmia in diabetic pregnancy. Their figures for the incidence of toxæmia in their series are vitiated by the absence of blood-pressure readings in many of the cases. Most workers would agree with Mengert and Laughlin[13] that the incidence of toxæmia is about 3 times as great in diabetics as in normal women.

Fœtal mortality-rates are given as 37% by Lawrence and Oakley and 44% by Barns, figures comparable with Joslin's pre-insulin rate of 44%. Four reasons are cited to explain these high rates: inadequate control of diabetes leading to hyperglycæmia or hypoglycæmia in either mother or child, toxæmia, asphyxia, and congenital abnormalities. Joslin[14] records congenital abnormalities in 8% of cases, Lawrence and Oakley found 2 examples in 54 cases, and Barns 3 in 25. The incidence of asphyxia is closely related to the mechanism of parturition, the age of the mother at the onset of pregnancy, and the size and viability of the fœtus. About a quarter of all cases of diabetes in women begin during the childbearing period, and 60% of these begin after the age of 30. In Barns's series the average age of diabetic primigravidæ was 33 years. Moreover, in diabetic mothers the fœtus is often large. Lawrence and Oakley report 27 out of 45 live babies with a birth weight exceeding 9 lb, and 23 of them were delivered by cæsarean section between the 36th and the 38th week of pregnancy. Abnormal carbohydrate metabolism is said to be responsible for these excessively large fœtuses. Lawrence and Oakley found that the average weight of babies spontaneously delivered in mothers with completely controlled diabetes was just under 7 lb, compared with an average weight of just over 10 lb in mothers with uncontrolled diabetes. Diabetes control is not the only factor determining size, however; they found that babies of diabetic mothers delivered at the 36–38th week by cæsarean section showed maturity in excess of normal more often than could be explained by an error in menstrual dates. Thus the infant of a diabetic seems to mature abnormally, and White attributes this to hormonal influences. Following up the work of Smith and Smith[15] on the relationship of blood prolan to the onset of toxæmia he has reduced the fœtal mortality in a recent series of diabetic pregnancies to 6% by substitution therapy with prolan and œstrone.[16] The previous best figure with equally adequate diabetes control (from the Boston group) was 32% fœtal mortality. It seems therefore that the early diagnosis and treatment of toxæmia offers the main hope of reducing the high mortality-rate in diabetic pregnancy.

The inheritance of diabetes is still unproven, and the view of Pincus and White[17] that it is inherited as a mendelian recessive is not accepted by all; but the hereditary trend exists, and must be considered when discussing the question of pregnancy with a diabetic patient. The prime factor to be considered must be the social one, the desire for a child in the family; the next essential is full coöperation of the patient. The added risk, the liability to fluctuations in diabetic control, the danger of toxæmia and of fœtal death, the

possible need for delivery by cæsarean section must all be explained With careful supervision by physician and obstetrician, attendance at least once a month for the first 6 months, and thereafter weekly, treatment of any sign of toxæmia, and cæsarean delivery between the 36th and 38th week, it is possible nowadays to offer the diabetic woman the chance of a live child with little more than double the risk of normal pregnancy

MULTIFORM RESEARCH

THE report of the governing body of the Lister Institute of Preventive Medicine, dated June 26, 1942, is full of meat Trade has been good, for the sales of sera, vaccines, &c increased during the year by £19,300 to £74,700 and far more than covered the whole expenditure But this passes almost unnoticed in a record of research, undaunted by circumstance, carried on by the three divisions of the institute scattered over the country Workers at Cambridge, Maidstone and Oxford may miss their library and their accustomed desks at Chelsea Bridge Road but the hospitality which they have enjoyed has been as stimulating to guests as to hosts The curator of the National Collection of Type Cultures has even been sharing quarters with his opposite number in the USA From the potted material in ten closely printed quarto pages only the all round expert would extract a complete diet, but even the general reader will find much food for thought Some of the more mature work has been published in 25 papers which have appeared in special journals and been abstracted briefly in our columns Their authors' names are household words in many lands The Vi antibody has been justifying its existence by proving as useful in detecting paratyphoid carriers as it has shown itself in the pursuit of outbreaks of typhoid fever, its practical value being enhanced by the fact that the Vi agglutination reaction is independent of the intermittency of bacillary excretion Some of the Vi phages have even been trained to develop strain specificity A serological test is proving useful for spotting *Trichomonas fœtus* infection in cattle Certain specific blood group haptens have been isolated from human saliva The *Clostridium welchii* has been shown to produce an enzyme which, like certain snake venoms, can break down lecithin The skin of fat starved rats is known to become thickened—mitosis in the epithelium is many times as great in them as in normal animals this research has thrown further light on the metabolism of linseed oil Human serum and plasma have been dried by a new process of freezing on a metal coil which is then dried in vacuo A method of removing lipoids from plasma by freezing with ether seems also to remove fibrin and may reduce the troubles of post filtration clotting There is some likelihood that hyaluronic acid contains preformed ring structures Work on hormones in rats confirms Minot's suspicion that the process of ageing starts very early, even indeed from birth , the diminution of the size of the nucleus in proportion to the containing cell also points in the same direction Vitamin standardisation is being pursued and a table compiled of the vitamin value of each of the common foods both for big agricultural programmes and dietary surveys The biological value of the proteins in various flours is being examined the loss due to lower digestibility in the higher extraction flours is more than compensated, it seems, by the higher value of their proteins A survey of potatoes shows great differences in total nitrogen content , but however high the content young rats will not flourish on this alone without a supplement of casein Nor can potatoes be substituted for barley in the diet of growing pigs without much added protein concentrate Dried brewers' yeast is as beneficial to pigs as is casein in supplementing cereal protein Household scraps are disappointing for obtaining live weight gain in pigs A biscuit daily containing 10 g of cultivated dried yeast has caused elementary school-children in Oxfordshire to put on w A dose of ascorbic acid 100 mg at intervals of se days or even weeks seems likely to offer additional tection against scurvy during the winter period report ends with an appreciation of the devoted coö tion of the director, Sir John Ledingham, and all mem of the staff under difficult conditions

THE FRACTURED SCAPHOID

THE diagnosis and treatment of fractures of carpal scaphoid in relation to Service conditions are summarised in the *Army Medical Directorate Bulletin* May This injury appears to be on the increase—it a not uncommon back-fire fracture—and the misdiagnosis of sprained wrist should become less frequent it is realised that a simple sprain in a young man is less likely than a scaphoid fracture It is important also to remember that the ordinary anteroposterior and lateral radiograms often fail to reveal a crack which is obvious in an oblique view, and that radiographic evidence may not be found in some cases until a few weeks have elapsed Early diagnosis is of cardinal importance in influencing results , the only problems are those arising from late recognition The recent case will unite with adequate plaster fixation (which includes the first metacarpal) until radiograms are satisfactory , there is no arbitrary period of fixation, and individual cases vary a good in the time required for union When the fracture first seen after 4–6 weeks, bone grafting by closed technique is recommended The Army authorities thus recognise that, while these late cases will often unite in plaster, the period of fixation may have to be very long It was to accelerate healing in these cases that Armstrong devised the operation, which has found considerable application in the Royal Air Force, where rapid rehabilitation of skilled personnel is of the greatest importance The operation, however, is not for casual performance; it must be carried out under strict radiographic control through a small incision over the scaphoid tubercle by a surgeon who has mastered the exacting technique A not uncommon problem arises when a wrist, perhaps recognised as always a little weak, is stirred up by trauma and an old fracture is discovered To treat this by immobilisation or grafting is not advisable under Service conditions , support and physiotherapy and an early return to duty are rather to be aimed at When an old fracture is associated with radiocarpal arthritis the bulletin recommends a similar line of treatment in mild cases , severe changes will require arthrodesis of the wrist, but this operation is hardly indicated for the serving soldier unless he is a key man When there is, at any stage, avascular necrosis the excision of a small proximal necrotic fragment gives a useful painless wrist, but excision of the whole bone has not been found to render a man fit for service again This bulletin, while it does not bring out anything essentially new, does emphasise two important findings—that neglect or misdiagnosis of what is still too often regarded as a trivial injury may lead to months of disability and uselessness , and that bone grafting in selected cases is of the greatest value in securing a rapid return to full function

---

1 Armstrong, J R *Lancet*, 1941, i, 537

Dr T Pearse Williams has gleaned the following from an essay on education by Oliver Goldsmith in *The Bee*, a weekly pamphlet, dated Nov 10, 1759

"No luxurious dishes with high seasoning, nothing given children to force an appetite, as little sugared or salted provisions as possible, though never so pleasing , but milk, morning and night, should be their constant food This diet would make them more healthy than any of those slops that are usually cooked by the mistress of a boarding-school , besides it corrects any consumptive habits, not unfrequently found amongst the children of city parents

CHOOL MEDICAL SERVICE IN WAR-TIME *

J ALISON GLOVER, C B E, M D CAMB, F R C P

IN the evacuation areas the school medical service was tirely suspended for some time after the first evacua- on Medical officers were in hospitals or aid-posts, urses had left in charge of special parties or as maternity urses or had gone to casualty hospitals, two-thirds f the schools had been taken for civil defence and the ther third were closed, nearly all teachers and every vailable social worker had gone with the evacuated hildren But only half or less of the children had left, he other half were still in the evacuation areas, having o school, no school meals or milk, and no medical ervice Moreover, there was a fear that to continue hese services in the evacuation areas would be to ncourage the return of children to them

THE CHILD WHO STAYED AT HOME

By November, 1939, conditions in the reception areas aving greatly improved, attention became focused on he large number of children left in or returned to the vacuation areas, whose condition—without schooling, neals, milk, or medical service—was deteriorating The Board of Education urged that the medical services hould be provided again and suggested, among other neans to cleanliness, that the excellent shower baths provided for gas decontamination, should be utilised Dr W S Booth, of Holland, Lincolnshire, had been the first to put them to this use Later mobile tented hower baths units were provided and staffed by Messrs Lever Brothers in the London area

Schooling was provided in successive stages first by "home circles" then, as shelters were provided and schools reopened, for children over 11, then for juniors, finally it was made compulsory for all children The children thus returning successively to school were medically examined There were some 180,000 children in London at the end of 1939, and by the withdrawal of the school medical and nursing staffs from the hospital service a school medical service was recommenced, 38 out of the original 80 treatment centres being reopened In the first 3 months of 1940, parents were invited by postcard to present their children for medical inspection and 58,000 children were thus inspected as well as 37,000 as the emergency schools reopened Cleansing, medical and dental treatment, and the provision of meals and milk began again Though there was some deterioration in cleanliness, health and nutrition, it was much less than might have been anticipated

From April to July, 1940, attention had to be concentrated on the children registered to take part in the second great evacuation scheme restricted to school-children and announced in February, 1940, this formed for months the main work of the school medical service, providing as it did for the registration, medical inspection, labelling, cleansing and keeping clean, and necessary treatment by the evacuation authorities of half the 1,100,000 children remaining in the evacuation areas At the same time the reception authorities were to arrange a further rapid medical examination on arrival, and were to prepare hostels for 2% of the total number allotted to their areas Parents were asked to register their children for it before the end of March, on the understanding that the children would not be sent away until bombing had begun, that they would go with their school parties, and that they would stay in the reception areas until the school party returned Only 239,000 children however, had been registered by June, and the fall of the Low Countries and France led to many changes On May 19, 1940, 34,000 London children who had been taken in the first evacuation to the East and South East coasts were transferred to South Wales, and a week later the local children from towns on those coasts most likely to be invaded were offered evacuation

Slight bombing began in May and 138,200 registered children had been sent out by July The real storm broke in September, 1940, a year later than had been expected, and evacuation was again opened to mothers with young children Children were evacuated in parties daily and later three times a week The tendency to drift back continued in ceaseless ebb and flow according to the persistence, fury or intermission of attack and greatly added to the difficulties of the service, as of all educational activities alike in evacuation and reception areas The number of children " remaining " in London varied from 262,000 after the first evacuation in September, 1939, to less than 85,000 in September, 1940, while on Jan 24, 1942, it was 166,900, and on March 7 180,600 The rate of return is still rapid, sometimes 2000 a week East Ham in peace-time has a normal roll of some 15,000 children, the numbers on the roll in 1940 varied between 9000 and 1500

In all evacuations after the first children had been carefully prepared and inspected before transfer, and complaints are now almost unheard, showing how well the school medical service has recovered from its initial shock, and how much was learned from the experience of the first evacuation The transfers entailed an immense amount of work accentuated in June, 1940 by the urgent demand for examination and treatment of some 17 000 children whose parents wished to take advantage of the scheme for sending children overseas Although a very small percentage of these children had gone overseas before the scheme had to be abandoned, these special examinations and treatment were by no means wasted The long remission of bombing since May, 1941, has enabled the service in the evacuation areas to return almost to normal

SCHOOL MEALS AND MILK

The provision of school meals and milk is one of the special services for which the medical branch of the Board of Education is responsible During the early part of the last war school feeding, especially in London, was extensive Soon, however, it rapidly declined both in London and the country generally probably owing to separation allowances and the current high wages In the present war, the pattern was reversed Evacuation caused a falling off, because feeding centres where the free meals were given were nearly all in evacuation areas and were closed Later, however, there was a great increase, mainly of meals on payment, and owing to the forward policy of the board and the Ministry of Food and the great demand for female labour this increase has been rapid Just before the war about 177,000 elementary children were having solid meals free, and probably about 50,000 on payment On a single day at the end of February, 1942, 448,500 elementary school-children took dinner at school, and 162,500 secondary school-children Thus in England and Wales some 611 000 school-children were having dinners in school, and, at the present rate of development, the number should be a million by September, 1942

As long ago as 1915 London set up a minimum value of 750 calories for the school dinner, which was also to have a minimum protein content of 25 g, two-thirds of it to be first class Minima have a knack of becoming standards, and these minima came to be regarded as standards for elementary school dinners throughout the country—standards moreover, which outside London were generally not attained Thus the prewar standard was largely unsatisfactory and the effect of rationing was to force school canteens to accept even lower standards Since the autumn of 1941 when the new scale of allowances for school canteens was adopted, however, improvement has been rapid

In November, 1941, the Board set up a new standard, this had an energy value of 1000 calories instead of 750, a first-class protein content of 20–25 g, instead of 16 6 g, and a fat minimum of 30 g The reasons for this advance in the midst of food restrictions are, first, that the average daily energy value of the food required by a healthy child of elementary school age is about 2500 calories, and secondly that the midday dinner which is for most children the main meal of the day should provide a good deal more than a third of the necessary calorie value, most of the necessary vitamins and minerals, and plenty of fat and first-class protein To reach this standard of first-class protein and to get enough calcium while keeping the charge within the *4d* or *5d* of the usual cost of the food, the 1 oz of dried milk allowed daily must be used for cooking, this valuable addition affords 11 g of first-class protein, 270 mg of calcium, 3 g of fat and has an energy value of 115 calories The Ministry of Food makes other valuable concessions to school canteens

---

* Extracts from a Chadwick lecture delivered on May 12, at the Royal Society of Tropical Medicine, London

Bulk cooking and vitamin-C preservation go ill together, as Dr S W Swindells has pointed out, and one of the difficult problems of the school canteen, especially in winter, is to supply adequate dosage of vitamin C Chopped raw vegetables added to each plate of the first course is a solution but demands a good deal of labour and some education of the children Many children still have to bring their own dinners to school, and the inadequacy of these lunches, so often exposed in peace-time, has been greatly accentuated by rationing, since almost every usual constituent of the sandwiches (meat, eggs, cheese, jam and butter) is rationed It is to be hoped that two of the good results of the war will be the inclusion of the school dinner as an essential part of the school curriculum, and the provision of school milk for every child

The milk in schools scheme received a great impetus from the rationing of milk as well as from intensive propaganda At the end of February, 1942, 3,113,000 children in elementary schools were taking milk under the milk in schools scheme, and of these nearly quarter of a million were having two-thirds of a pint daily, so that whereas in 1938–39 some 55 6% of all elementary school-children were receiving milk either free (11 5%) or at a reduced price, now not less than 75% of all elementary school-children are getting a third of a pint or more a day in school, in addition to the half pint of fresh milk at the ordinary price to which they are entitled under the priority scheme The priority policy however, though it allows and encourages, does not by itself *ensure* a larger milk-supply to school-children It is, therefore, essential that all school-children should receive the extra milk provided by the milk in schools scheme In addition to the numbers in elementary schools, 275,800 children in secondary schools are receiving milk in school under the scheme

CAMP SCHOOLS

In 1939 the National Camps Corporation built 31 camps in delightfully rural surroundings, 30 of which are now occupied as residential schools Originally designed for short-stay school camps for 348 children, the standard model had 6 long dormitories with 58 children sleeping in double-tier beds, a dining-hall with kitchen, an assembly hall, two ablution blocks, a hut with three classrooms, and a hospital block with 7 beds For permanent occupation as boarding schools for 240 children over 11 years, one dormitory has been converted into class or workrooms, and the number of children in each dormitory has been reduced to 48, while the hospital beds have been increased to 11 The dining-hall, kitchen and dietary are admirable, and the health of the children during the past severe winter has been remarkably good Elementary school-children have thus been given some taste of the advantages of country and open-air, ample well-balanced meals, regular hours and adequate sleep The education of the future will owe much to the energy, foresight, and wise choice of sites of Sir Edward Howarth, and his appreciation of the importance of feeding arrangements in education The children have grown remarkably tough and have developed a pride in their health I visited one camp of 200 children after 3 weeks of severe winter weather in a high and exposed position, and found the hospital block empty, only 3 children had been admitted for trivial ailments during the previous month

In England Now

A Running Commentary by Peripatetic Correspondents

WHEN W H Hudson wrote his essay on "The great dog superstition," he can scarcely have realised how great was the prejudice to which he was opposing himself, how strong the bulwarks of canine liberty If any exacting experiment has to be carried out, its proposer soon finds that dogs are sacrosanct (not to mention the felidæ and equidæ), and if frogs will not serve his purpose he must fall back on human volunteers, who share with frogs and invertebrate creatures the legal presumption that they can look after themselves The holder of a licence under 39 and 40 Vict, cap 77, may vary the constitution of an animal's diet, but not so as to prevent it from satisfying its hunger or thirst, so that experimental work on dehydration has almost of necessity to be carried out on the human species Fiat experimentum in corpore vili!

A personal experience of three days' dehydration has enabled us (*pace* A P Herbert) to "check up on" the subjective aspect of water lack, and, as generally happens, experience was at variance with some of the published accounts For instance, Byron talks of

> "The incessant fever of that arid thirst
> Which welcomes as a well the cloud that burst
> Above their naked heads"

Now, dehydration produces no febrile state, and thirst in overmastering force is experienced only after exercise of a type which would produce the desire for water in a normal person—for example, on the first day of dehydration, after the unwonted physical trauma of a sixteen mile walk, and the psychological trauma (to a waterless person) of watering a compost heap, thirst was more acute than at any later time As to the welcome predicted for a cloudburst, the reaction to rain (at any rate when dehydration is self-inflicted) is the usual ungrateful one of involuntary mild annoyance that human comfort is being subordinated to the less clamant needs of the plant kingdom Coleridge says

> "Through utter drought, all dumb we stood!
> I bit my arm, I sucked the blood,
> And cried, 'A sail! A sail!'"

and in another place

> "We could not speak, no more than if
> We had been choked with soot"

Though we have had our little difficulties with venepuncture, we have not yet been driven to biting the arm as a method of withdrawing blood, but we found that to restore moisture to the parched throat much larger amounts of fluid were required than would be likely to reward the amateur dental phlebotomist We found that when the mouth and throat became really dry there was some alteration in the voice, being choked with soot sounds worse than anything we encountered in the dehydration period Thirst was not tyrannical in its mastery of consciousness, but it was rather literally tantalising to assist at meals, where colleagues drank what appeared to be quite extravagant amounts of water coffee and tea (Why had I never noticed before how richly endowed the streets of X are with ale houses? No detour can avoid them Do the authorities ever refuse a licence?) To food one became strangely indifferent, except things like oatcakes, which foolish preliminary optimism had chosen as part of the diet, and which later aroused a passion of antagonism

The most notable subjective effect of dehydration was the almost intolerable slowing of time One felt that this business would never end—books talk and work were of little benefit Perhaps it was my share of the collective unconscious which impelled me to the cinema on two successive evenings This did help to liquidate a portion of time, though I responded poorly to questions as to what I had seen, one of the things was in luscious Technicolor, and in another almost all dialogue started with "Have a drink" After this experience of almost invincible boredom, I shall never again question the world-without-end hour, and if any poet comes to me and says "Oh, for an engine to keep back all clocks," I shall prescribe three days of dehydration, with 4 oz of oatcake t d s

If some Master Maeterlinck, looking down on our t-hill, possibly brooding on what specific name to give —"Homo sanguineus, hardly, destruens, no-o, ternans, that's better"—happens to spot our planners, will surely smile The urge for planning is interesting iat it is a non-combatant's war-liberated energy eking expression seems obvious, that the older and dentary feel it more, that the busiest by no means cape it (e g, Lloyd George, who at a critical phase in ie last war suddenly wanted to nationalise the drink ade), that it is a constructive reaction against the astes of war, all this seems certain That subcon-iously (Lord, how I hate that arrogant word which iplies one knows where in an old horse-pond the water ids and the mud begins) it is an effort to keep power the hands of the planners themselves, which threat is evoked the young planners, I have no doubt whatver Perhaps the urge to plan is an instinctive buffer gainst reaction I say "instinctive' because it is an nazing fact that all the planners seem studiously to nore the certainty, the tidal certainty, of reaction o-one would think that these same planners had lived rough another war, when a like high purpose ruled us, nd yet within a decade Ramsay MacDonald was prime inister, "conchies" crowned with laurels, war books nsaleable, valour dross They seem blind to the past nd to have very little insight Yet reaction will come ith mathematical precision, the more Cromwellian our iood now the more libidinous the Restoration Person-lly I think it will take the form of rebellion against all ate control, of increased individualism In my own ind I feel its fœtal stirring in phantasy Act 1 is illed "The Return of the Warriors," the steady grim amp of tattered men and women in procession I am anding in the crowd watching them and a helpful oliceman is explaining "Wher're they going? Why, ie meet's in Trafalgar Square and most of 'em are rawing the Whitehall coverts That savage looking it there, them with the long knives, they're the Malayan risoners whose wives have been on the public assistance 'hey're 'unting the Colonial Secretary, they are, but iost of 'em want Lord Paperwaster and Frederick 'orm-Ffiller Those are the young doctors there, raving their listening toobes " Act 2 is called The End of the Bureaucrats," and for this I have aked up some of childhood's scenery, made during a irst lesson in the village church It depicts an oriental ourtyard, and a wigged woman with a painted face vithdraws from an upper window as the warriors enter —"And he lifted up his face to the window and said, Who is on my side? who? And there looked out to him wo or three eunuchs And he said, Throw her down " don't know if there is a courtyard at the Colonial Office, out there's a beauty in Tavistock Square Act 3 has yet o be written I hope by the warriors themselves

* * *

Recently we had a terrible terrifying questioning from he Ministry of Health which aims at obtaining informa-ion about the medical schools of the future, to deal vith this adequately would be a whole-time job of a ortnight at least Then London University has asked is to draw up schemes for the Utopia of hospitals and nedical schools and we have met three times already o express our nebulous conceptions I am for the most part a listener, having at the outset exploded violently vith the opinion that I wish we all got on a little faster vith the war and bothered less about what we are going o do when we have won it I admit that some sort of skeleton scheme is desirable, but I don't sympathise vith the game of clothing the skeleton's dry bones with ill superficial structures and then adorning it with laborate habiliments which the mistakes of the past iave encouraged us to avoid or to add In its third year of war our medical school has carried on with absolutely no alteration in the position established welve months ago We are full to capacity, many applicants have to be refused The arrangements at parent and sector hospitals have been maintained Naturally we suffer from the drain on available teachers is the Services' requirements inexorably press-gang the men of the registrar class and some of the junior members of the staff Those who are left have been working continuously with ever increasing claims on their time And they are very weary So far as examination results are a criterion we may be said to have done our job satisfactorily, but I personally am wondering all the time how much longer we can last

* * *

I realised the other day that I had been educated for over twenty years, and perhaps even longer The earliest part is a little vague now, and all that I remember is that it was at a kindergarten called Gwendon At one time or another two of its pupils were buried in a sand-tunnel they had made, thus restricting our playing area And another thing was a girl called Rosemary, with whom I was silently in love Ah, but she was lovely From that time I have been educated without ceasing, and I cannot for the life of me decide what I have learnt I passed my Anatomy and Physiology, and I can read English French, American, Latin and Greek, which must be a good show But twenty years

A lot of it too—and this certainly makes it worse—was done on scholarships At my prep school, where I was a nasty blubbing little boy, never ready enough with "ego" and "ne no fains," I early discovered I had no aptitude for games Swotting was the only occupation open to me, and I swotted If you swot it is easy to get a scholarship, especially in one of the more recondite languages I earned more for knowing Latin than I could have hoped to win by doing something useful—mining, for instance or fighting in a war This seems to me ridiculous in retrospect, but I still have a scholarship today They have even extended my period of uselessness, since I could not switch to medicine till the classics had outworn their financial benefit

Of course, I really do not feel bitterly about this at all The years have been highly delightful, I would have them again all but the last three, with the greatest of pleasure It just seems to me uneconomic and I wish, no doubt largely because the Government forbids it, I could take part in the war It seems to me, too, that there were times when I learnt much more quickly than at others, most notably in the United States There, with everyone who taught us doing some sort of research and liking it, we easily caught the fever No-one ever cut lectures if they could help it, which is a record few schools and universities over here could boast There was an excitement in learning, which there presumably ought to be Occasionally in this country it has been possible to feel that it would be much quicker to read the books instead of hearing them recited

Twenty years And it is not over yet, nor will be unless singular courtesy is shown by my examiners One thing only has reassured me recently, I found, looking through the old notes of our hospital, a student who did not know how to use exclamation marks He put them in everywhere! His report ends on one of the most excited notes imaginable Urine! Yellow! Clear! Acid! No Sugar! Albumen—Nill! I doubt if he was even educated for fifteen

* * *

The theatre was magnificent and the lighting superb Cloth after cloth, of colours as multitudinous as those of a Connecticut autumn, draped the edges of the wound We stood well back, in order not to be noticed Everyone wore white boots The anæsthetic trolley was so ingenious that the anæsthetist not only could but actually did, read a book (A book on anæsthetics, I saw to my surprise) Everything was so quiet and neat that you could have believed yourself in heaven instruments being passed at the right time viscera popping out and popping in But suddenly my heart missed a beat A surgeon, an assistant, a registrar, an anæsthetist, a sister, six nurses, two students, thirteen in all And then I felt it steady again Of course Stupid of me The patient

---

Messrs Boots now issue their brand of sulphaguanidine in 0 5 g tablets In the treatment of bacillary dysentery they recommend an initial dose of 0 1 g per kg body weight for adults or children In adults this is followed by 0 05 g per kg every four hours until there are less than 5 stools in 24 hours, and then by 0 05 g every eight hours for another 48–72 hours In adults the maintenance dosage recommended is 0 05 g per kg body weight every eight hours, continued for not less than three days after the number of stools has fallen to less than 5 in 24 hours Messrs Boots are also issuing iodoxyl (*BP*) for excretion pyelography under the name of 'Urumbrin,' in 3 c cm and 20 c cm ampoules

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS, M P

THE long-expected debate on the Ministry of Health which took place on June 30 was, politically speaking, overshadowed by the war debates of the two following days But, characteristically, the health debate was level-headed and unaffected by the currents of opposing ideas that were clashing and conflicting in smoking-room, dining-room, lobby and committee rooms of the House

Mr Ernest Brown had a good account to give to the nation Despite war, despite rationing, despite long hours of work the health of the nation was better in 1941 and the first quarter of 1942 than in the year before the war And, very significantly, not only was health better but the birth-rate in the first quarter of 1942 established a record The debate ranged over many topics—special attention was paid to tuberculosis—but there was a strong bias towards what the Minister called positive health, which is something more than preventive medicine and Mr Brown paid tribute to the work of Sir Wilson Jameson in awakening the nation's health conscience But indeed there is no field of health administration from prophylaxis against diphtheria to planning for post-war medical relief in which Sir Wilson has not done admirable work

The story of the epidemic diseases is remarkable There has been a rise in venereal disease, not as great as that of 1914–18, but there has been a fall in diphtheria and a fall in the death-rate The rise in notifications of cerebrospinal fever is balanced by a considerable fall in the death-rate Unexpectedly perhaps, there has been a decline in admissions to mental hospitals and one wonders if this is due to a passing phase or to deeper mental and physical causes Tuberculosis is to be attacked by the extension of early diagnosis by miniature radiography and a comprehensive rehabilitation policy, but the Minister admitted that treatment is handicapped by the difficulty of getting nurses South Wales has vacant beds and a waiting-list of cases needing treatment They cannot be brought together because there are not the nurses to do the job The Minister estimates that he wants another 12,000 nurses but he and the House were unwilling to obtain them by compulsory enrolment of registered women

Mr Brown's references to the future of our hospitals and the interim report of the BMA planning committee were cautiously phrased and non-committal No doubt we shall see what we shall see and the Government may, although it was not suggested, produce a scheme of their own Probably indeed the Government of the day will have to produce its plan at the end of the war, but then no-one knows what kind of Government that will be

In the debate Sir Francis Fremantle made one of the best speeches he has ever made in the House He spoke of the three shortages beds for maternity cases, beds for tuberculous cases, and personnel He urged the need for rehabilitation after sanatorium treatment for tuberculosis He also proposed that we should deal with venereal disease as we do with other diseases—take power to treat them as infectious and prevent men and women going about and infecting others "We must compel people to undergo treatment" At the end of the speech Mr Messer, well known for his hospital administration in Middlesex, said that he was almost inclined to call Sir Francis "Comrade"

A good debate, perhaps a little optimistic, but at least showing a people in excellent state to endure the more rigorous conditions and real austerity which war may yet impose upon us

Pensions for Seamen

Noble Lords added the following clause to the Pensions (Mercantile Marine) Bill on July 1

> For the removal of doubt it is hereby declared that the expression "physical injury," in the principal Act and in this Act and in the Personal Injuries (Emergency Provisions) Act 1939, includes tuberculosis and any other organic disease and the aggravation thereof

The new clause takes the place of the amendment put forward by the Earl of CORK and ORRERY, and is a tribute to his pertinacity and enthusiasm on behalf of the merchant seaman

FROM THE PRESS GALLERY

Minister's Survey of National Health

GOOD health, like peace does not make headline is war and disease which provide sensation But Minister's report in the Commons on June 30 on nation's health gives us cause for sober gratitude T total grant made by the Exchequer to the Ministry f the coming year is £266 500,000, and we are getting value for our money True we have no adequate statistical test for positive health, but the records of birth deaths and notifications of infectious diseases show th after a thousand days of war in many ways we healthier than we were in peace-time

CAUSE FOR SOBER GRATITUDE

The birth-rate for 1941 was 14 2, compared with 15 in 1938 and 20 9 in 1916 For the first quarter of 194 the rate was 15 5, the highest rate in any March quart since 1931 The infant mortality-rate for 1941 was *compared with 53 in 1938 and 91 in 1916* The rate f the first quarter of 1942 was 61, the lowest March quarter rate on record The maternal mortality-rate was 2 as compared with 2 97 in 1936 and 4 12 in 1916 Thus *though the birth-rate had been falling,* the survival rate had been increased The crude general death rate was 12 9 in 1941 as compared with 11 6 (which was the lowest on record) in 1938 and 14 4 in 1916 Epidemics called for special care in war-time Dislocation of conditions of living, the congregation of all sorts, tions and ages of people in billets and shelters, the risk of damage to water-supplies had been new factors But statistics showed that during the war the rate of infectious disease had been, with certain exceptions, below the average After centuries of fatalistic suffering we have found ways of mastering epidemic diseases Mr Brown was sure the health education work of the Ministry, the medical profession and public health authorities had a great place in making good practice well known

Apart from tuberculosis, the only infectious disease which had shown a rise was *cerebrospinal fever* In 19 there were about 2000 cases, and in 1938 and 1939 there were about 1300 and 1500 cases, respectively But in 1940 nearly 13,000 cases were notified and in 1941 over 11,000 For the first half year of this year there had been approximately 4000 cases compared with 7000 in the first half of last year and 8000 in the first half of 194 But the fatality of the disease had been reduced from 69% in 1935 to 34% and 20%

The incidence of *diphtheria*—the chief killing disease among children of 4–10—has not fluctuated widely during the last 25 years, there were 53,000 cases in 191 and 50,000 in 1941, but deaths had fallen from 5300 in 1916 to 2600 in 1941 The Ministry had been pressing a campaign for the immunisation of children against diphtheria and by the end of 1941 a third of the child population under 15 in England and Wales had been immunised The authorities in Scotland had done better than that and Mr Brown was not satisfied It three-quarters of our children could be made immune diphtheria *as a fatal* disease would disappear present on an average day 4000 beds were occupied by diphtheria cases The main difficulty in making pro gress with immunisation lay with the parents and wanted quicker cooperation

Scarlet fever was now a scourge of the past In 19 there were 130,000 cases, but the mortality had already fallen to 2100 In 1941 there were 59,000 cases and only 133 deaths *Enteric fevers* were natural sources anxiety in war-time, but in 1941 there were under 50 cases and 118 deaths compared with 6000 cases and 1100 deaths in 1916 It was interesting that not one of these deaths in heavy bombing years was due pollution by water-borne infection There were deaths from *pneumonia* than from all the other infectious diseases combined except tuberculosis In 1941 there were 50,000 cases notified and 26,000 deaths compared *with 23,000 deaths in 1939 and 29,000* in 1940 Pne monia was not notifiable till 1919, but there were 38,0 deaths in 1916 and 59,000 in 1918

AND FOR RENEWED EFFORT

An increase in *venereal diseases* was not unexpe but it was not so great as in the last war Existing vices had been expanded—p aganda is being ued, but the work limiting the spread of infection was mpered by the lack of powers to deal with people who ere unwilling to have treatment *Scabies* was already the increase before the war, and it continued to grow ith the redistribution of population until its incidence eant a substantial loss to production It was really a usehold disease and the investigation of home condi- ons and the follow-up of contacts were essential, and owers to this end had been taken last year There were accurate figures as to incidence, but the latest impres- on was that the increase had been checked

Our *mental hospitals* had their own war-time diffi- lties A number of institutions were surrendered at e beginning of the war to the Emergency Medical ervice As in others there had been overcrowding and ortage of nursing and domestic staff But on the her hand there had been a decline in the number of w cases admitted It had been feared that the strain war would lead to a serious increase in mental dis- ders, but the contrary had proved to be true In 1938 e number of cases admitted was 30 000 and in 1939 it as again 30,000 In 1940 it fell to 28 000 and in 1941 26,000—an eloquent testimony to the nerves of the tion

Finally *tuberculosis* was causing him some concern— d he used the word in the sense in which the Friends se it, with real meaning The number of deaths was ,669 in 1941 compared with 28,144 in 1940, 26,176 in 38, and 53,858 in 1916 The steady fall in tuberculosis the twenty years of peace had been interrupted It as obvious that there existed conditions in war-time hich predisposed to this disease, but looking to the roblem as a whole, Mr. Brown thought we must review ur general approach and give greater practical effect the need for early diagnosis In the past we had nded to concentrate on treatment, but miniature diography was a new and useful weapon of which the llest advantage should be taken He had ordered a umber of sets both from America and from makers in his country, which he would make available to local uthorities as a part of their tuberculosis schemes teps were being taken to see that trained teams were vailable to handle these machines, and he hoped that owards the end of the year they would be in use

We must also tackle the problem of aftercare and ehabilitation on more comprehensive lines Beds for uberculous patients had been available out of the mergency hospital pool, but it was difficult to find ursing and domestic staff No one wanted to use com- ulsion, and they had sought to secure the necessary taffs by propaganda and persuasion and through the goodwill of the professional organisations The number of state-registered nurses at the end of April, 1939, was 4,200 Three years later it was 103,700, so there has hus been a rise in the actual number of nurses, and Mr Brown averred there was not a national shortage out particular shortages of nurses in particular places, nd especially a particular shortage for particular services But on being pressed he admitted that on the whole field of the nation he could do with another 12,000 nurses, and for the tuberculosis services he needed an immediate nrolment of 1200 nurses The London County Council had attacked the problem by making periods of work in a sanatorium a regular feature of the work of their nurses This procedure might be more widely followed, hough it was not free from difficulty We could not afford to fail in the treatment of tuberculosis because patients could not be nursed, and in the last resort he might have to consider a wider exercise of his powers of direction than had hitherto been applied, but if the needs of the situation were properly understood he did not think that would be necessary Nursing was a pro- ession, which like that of medicine, had its special risks and those risks were willingly faced He was advised however, that there was no ground for the belief that nursing in sanatoria need involve any greater risk of contracting tuberculosis than nursing in other hospitals It was in the last year of the last war that the most serious effects on the nation's health were shown—the sharp rise in the incidence of tuberculosis and the pandemic influenza—and we must be on the alert and take measures against such a catastrophe But it was clear that the amount of medical attention that the civil population could ask for must be limited The medical profession had had to meet large calls for the needs of the forces As a nation we must do what we could to get along with less medical attention, but he would concentrate on maintaining those essential services which were vital to the health of the nation

But the Ministry has also an eye for the future And Mr Brown described the watch he is keeping on the food situation from the health point of view through his regional medical officers, the Emergency Hospital Service and by special local surveys which had been undertaken with the help and guidance of two expert medical officers supplied by the International Health Division of the Rockefeller Foundation, the Medical Research Council and the University of Oxford They had also started a hospital survey and he had examined with interest the draft report of the British Medical Association Under Lord Rushcliffe the two committees on nurses and midwives were making great progress They were preparing plans so that the moment labour and material were available they might resume their onward march in housing The Ministry of Health was also playing an active part in connexion with post-war relief in Europe which was being considered by an inter-Allied committee under the presidency of Sir Frederick Leith-Ross The technical aspects of medical relief and nutrition were to be examined by expert subcommittees A good deal of preliminary work had already been done on the requirements of essential drugs in the immediate post-war period and for any possible campaign against epidemics, typhus and malaria

Members' Views on the Health Survey

Mr CLEMENT DAVIES pointed out that we spent over £300 million on our health services, two-thirds went on cures and only one-third on the prevention of ill health Tuberculosis affected us all from Land's End to John o'Groats, yet we were still treating it locally instead of nationally For instance in South Wales five counties and two county boroughs had not adopted a scheme for aftercare It was wrong that the health of a man or woman should depend on the accident of geography He asked for one standard of treatment for the whole of England and Wales Our lack of nurses was due to bad pay and bad amenities, and he believed we could put the whole matter right by putting the amenities right We must change our outlook on poverty At present our laws were for the protection of property, and not for the protection of health Lady ASTOR pleaded for more and better nurseries and nursery schools, and Mr JAMES GRIFFITHS, speaking as chairman of the advisory committee on youth in Wales of the Board of Education, put forward the claims of the adolescent Excessive hours of work were undermining the health of our young people, and he was concerned at the depletion of medical services in the industrial areas He urged that every nurse or domestic worker in a sanatorium should be sure of having a room of her own

Sir FRANCIS FREMANTLE pointed out that the shortage of maternity beds and of institutional beds for tuberculosis were problems not easily solved during war-time. There remained shortage of staff The Athlone committee, of which he was a member, seemed to have gone into hibernation, but he expected great developments from the Reports of the Rushcliffe Committees The public were beginning to realise the importance of prevention and rehabilitation and their education in this direction must be continued so that they would be willing to pay their share of the cost Cases must be followed up, and the doctors in the hospitals, the outside nurses and health visitors ought all to be linked up organically If rehabilitation was to succeed it must be done by arrangement with industry Sir Francis felt that post-war plans should not be too precise so that those away on service might take part in the final discussions He urged that powers should be taken to compel people with venereal diseases to go for treatment Sir DERRICK GUNSTON has never understood how we could spend so many millions on health services and yet spend so little on our nurses' wages Mr H C CHARLETON asked the Minister to push the Board of Control overboard and himself undertake even wider duties The active treatment of the mental patient had lately developed and he hoped that the Minister would start to organise these scattered experiments The Board of Control was supposed to visit mental defectives under guardianship, but he knew of cases where there had been no board of control inspection for as long as five years Dr Russell Thomas did not want to see the old relation between doctor and patient altered A doctor, worshipping at the shrine of the statistics of bureaucracy, could forget his patient

Mr H McNeil and Sir Ernest Shepperson joined in the appeal for an active policy to stem the rising tide of tuberculosis Dr Edith Summerskill pointed to the prevalence of non-pulmonary tuberculosis among children and asserted that on a conservative estimate 40% of these cases were due to infected milk Evacuated children in country areas were now consuming unpasteurised milk She also asked the Minister to make it compulsory for local authorities to teach their midwives to administer anæsthetics After four years only 66 out of 188 local authorities were using their powers in this regard although there was a safe portable apparatus on the market Captain G S Elliston was disappointed at the result of the national appeal for diphtheria immunisation, and Mr D J Quibell deplored that trained maternity nurses were being transferred into industry to give first-aid Dr H B Morgan admitted that good work was done by the voluntary hospitals but condemned them as "undemocratic and unrepresentative organisations ' Great tragedies, he said, sometimes happened in voluntary hospitals and no proper investigations could be obtained What we needed was one unified national system of hospitals The Minister was sheltering behind those who were attached to teaching schools Dr Morgan had no complaint against teaching schools, but there was no reason why the voluntary hospitals attached to them should not come under a national authority subject to Parliament The Ministry, he continued, was dead as far as rehabilitation was concerned and he did not propose to rattle the bones He had done his best, he cheerfully added, to awaken the poisoned corpse and failed But in spite of these macabre asides he wound up by paying a sincere tribute to the Minister and his parliamentary secretary and urging them to sit down and devise a comprehensive scheme under which local authorities would have powers for the prevention diagnosis, treatment and cure of tuberculosis Mr D L Lipson thought the housing position was far from satisfactory and Mr K Lindsay asked for a real charter for youth

Mr G S Woods said the debate had dealt with everybody except the patients

Miss F Horsbrugh closed the debate with replies to some of the points raised She promised the biggest housing drive possible at the earliest possible moment The prime necessity for dental treatment was an expansion in the number of dentists and dental mechanics The Minister had done a great deal to induce local authorities to give instruction to midwives in administering anæsthetics to women in childbirth, but he had no power to force them The matter of trained midwives going into the Services was being looked into with a view to retaining them in civil practice There were now 90,000 nurses, student nurses and nursing auxiliaries working in civilian hospitals, including isolation hospitals and sanatoria which took both Service and civilian casualties That was 8000 more than at this time last year, and she wished to see another 12,000 nurses provided to get over the 100,000 mark in the hospitals If they could get 1000 or 1200 nurses into sanatoria they would be all right They were looking to the Minister of Labour to see that more people undertook domestic work in hospitals and sanatoria Nothing definite could be said about after-care until the report of the committee of the Medical Research Council was received She would look into the question of the price of insulin, which Mr G Griffiths had raised, especially as it affected people who were not insured

" I have treated all kinds of diseases that I know the names of, and a lot of them I don't know, I suppose Wild Welch bacillus is just one of about five thousand foreign bacillus that gets in the colon It is supposed to come from wild Welch rabbits "—Testimony of Hiel Eugene Crum, a doctor of naturopathy, before the Indiana State Board of Medical Registration *J Amer med Ass* May 9, 1942, p 204

Letters to the Editor

DIFFERENTIAL DIAGNOSIS OF DYSPEPSIA

Sir,—The report on 217 Service cases of dyspepsia Morton Gill Berridge, and Arden Jones published your issue of June 20 fully justifies the decision of Director-General EMS to give them control of a s section of a hospital for their work Their results are great interest, but some of their conclusions seem to us be based on insufficient evidence

(1) Contrary to our experience and to that of other physicians they regard gastritis as the cause severe symptoms which are very resistant to treatment, whereas we believe that a large majority of cases are completely latent and the remainder get well rapidly with simple diet, together with lavage of the fasting stomach when associated with hypochlorhydria and excessive secretion of mucus If the causes, such as insufficient masticatory surface, septic teeth, excessive smoking and gross dietetic errors, are removed, recurrence is rare. The contrary experience of Dr Morton Gill and his colleagues is doubtless due to the fact that they were dealing with patients suffering from exhaustion or anxiety, which expressed itself in dyspeptic symptoms because of the associated gastritis, to cure them they required simple psychotherapy in the form of explanation in language suited to their intelligence, persuasion and re-education - With a predisposition to circulatory insufficiency the same patients would have developed the effort syndrome

(2) With regard to duodenitis we are not convinced that the diagnosis is justified by the radiological observations of Cordiner and Calthrop, whose mucosal relief methods had been used by Scott and by Briggs several years before Berg's work became known in this country. The radiological diagnosis of gastritis can be controlled by gastroscopy, which has shown how unreliable it is. The radiological diagnosis of duodenitis has never yet been confirmed, and it is difficult to see how anything short of quite unjustifiable surgery in the form of duodenectomy could ever confirm it The statement that "ulcers complicating duodenitis are usually superficial and appear to be implanted on the swollen rugæ' and that "they often heal rapidly leaving the duodenitis still present and apparently active" appears to be purely imaginative We are quite unfamiliar with the clinical picture with its dismal prognosis which Morton Gill and his colleagues draw of this condition either among civilians or soldiers

(3) Although only one case was diagnosed as mucous colitis, it would be of interest to know what is meant by this, as mucous colitis is in our opinion a quite mythical malady

(4) In six cases looping of the first part of the duodenum was thought to be related to the dyspeptic symptoms It seems incredible that this is anything more than an anatomical variation from the normal of no greater importance than those other mythical maladies, gastroptosis and enteroptosis, which happily do not appear among the diagnoses in this series of cases

(5) The fact that not a single case of chronic cholecystitis was found among 217 dyspeptic soldiers shows that the possible presence of this common condition could not have been sufficiently borne in mind, as a careful clinical investigation with a properly carried out examination of the gall-bladder contents could hardly have failed to reveal several cases of the kind

(6) Morton Gill and his colleagues state that at present many men are returned to duty with the diagnosis of non-organic dyspepsia in the hope that they can be persuaded to tolerate their symptoms, and that failure to recognise these as genuine must create in their minds a growing sense of injustice and dissatisfaction Of course their symptoms are genuine, and we feel convinced that most, if not all, of them could be quickly cured if simple psychotherapy from their own medical officers, but not from a psychological specialist, were substituted for dieting which they cannot carry out under Service conditions

EATMENT OF THE "CRUSH SYNDROME"

IR,—In June of last year we brought forward lence to suggest that the approach to the problem of "crush syndrome" had previously been from a ng basis, and that the condition including its renal nifestations was the result primarily, not of toxæmia simply of the loss of blood constituents into the ured limb, the capillaries of which had temporarily their function Applying this conception thera-tically we argued that the primary principle of atment should be to stop the limb swelling, or if was swollen to reduce the œdema This we achieved applying positive pressure of 60 mm Hg to the limb published details of two cases successfully treated on se lines (*Lancet*, 1941, i 780)

Strong experimental support for our theory has ently been furnished by Duncan and Blalock (*Ann rg* 1942, 115, 684) By compressing the limbs of dogs a special clamp, they have produced a syndrome nilar to the crush syndrome of man, including shock d renal failure Untreated 18 out of 19 dogs died t when the damaged limbs immediately after release m compression were enclosed in a pneumatic tube th a pressure of 40 mm Hg 15 out of 21 dogs survived Further experimental work is clearly required, par-ularly to elucidate the mechanism of production of e renal symptoms We suggest, however, that there now sufficient evidence to justify routine prophylactic eatment being standardised on the lines advocated in r article If this view is accepted, first-aid workers ould be instructed to bandage firmly the limb as soon it has been released Immediate treatment on the me lines should be carried out in hospital either with e apparatus we suggested or some modification which lfils the same principles The present lull in aerial mbardment in many districts offers a suitable portunity for working out the requisite measures of ganisation

The Middlesex Hospital, W 1   J DOUGLAS ROBERTSON

REACTIONS TO THE REPORT

SIR,—May your erstwhile special commissioner, his personal capacity, congratulate the BMA Medical lanning Commission on their draft interim report? he striking reforms which it proposes, and with which think most younger doctors will agree, are

1 A complete medical service for 90% of the population
2 A substantial measure of free choice of home doctor
3 A substantial improvement in the conditions of work and therefore in the standard of possible service) of the home loctor, including a period of apprenticeship in a health centre, he abolition of sale of practices, appointment on merit, ontributory pensions, full professional coöperation, and an ncreasing part in preventive medical services (ante and post-atal work, school medicine and immunisation services)
4 In return, the home doctor will relinquish his consultant nd specialist activities to those who are specially qualified nd continuously practising the specialties
5 A regional hospital service, with full time and part ime clinical posts, and a domiciliary consultant service
6 In both general and special practice, the clinician is to e equal with and not subordinate to the administrator, both n status and remuneration, and a democratic medical ommunity is to be assured

Are there good and sufficient reasons for excluding he "upper 10%"? Among this group there are many eople who prefer private contract, but there are also nany who would welcome the opportunity of joining he National Medical Service The burdens of sickness re often proportionally heavier on those earning £420 year and upwards than on the lower income groups Surely, the common-sense answer is to open the National Medical Service voluntarily to the "over £420s"

The question of social medicine as a factor in positive health is not considered By social medicine one does not mean anything mysterious or "high falutin," but rather the prevention of poverty, whether due to sickness, disablement large families, old age, or unemployment If we can abolish poverty, we shall have largely overcome the problems of suboptimal nutrition, apart altogether from the mental results of financial insecurity At the same time, new problems in the prevention of exploitation will arise as a result of deliberate absenteeism and refusal to work, and feigned or hysterical illness The solution is not to be found in more and better medical boards but rather in transferring the responsibility for these decisions to committees of the worker's equals Such committees should hear medical evidence, and are inherently likely to give reasonable decisions which will have the sanction of the workers' own society This has in fact been the war-time answer to the problem of absenteeism, judgment on the offender is passed by the works production committee, often with a worker in the chair

The proposed links between the National Medical Service and the public which it serves are not of a very direct and personal nature The war has brought home to many of us that the British public will always cooperate if approached cooperatively If one is prepared to listen patiently to all complaints and explain difficulties, the feeling of partnership in enterprise is built up There is room for local health committees in areas served by each small group of health centres Such committees can act as valuable channels for receiving information from the public and also imparting it in a personal and direct way A working war-time example of such a service is the local information committees of the Ministry of Information

The rôle of the medical officer of health is not defined He is to be shorn of his clinical duties What is he to become? His special function should be that of the "*social doctor*," with the rank of a specialist on the staff of the local or group hospital, available for consultation with the home doctor whenever environment appears to be implicated He should keep the statistical picture of the health of the area, and provide a health intelligence service, while retaining his functions in connexion with advice on environmental matters to local authorities

There is a long and hard road to be travelled between the draft interim report and the Statute Book One hopes that the report may be strengthened—or at least not watered down—in its passage through the commission and the association Beyond that lies a stiff job of lay education—first among the ordinary public, secondly among the legislature and the central government officials, and last, but by no means least, among the local authorities

London   STEPHEN TAYLOR

COTTON LIGATURES

SIR,—In support of Professor Pannett's plea for the extended use of cotton as ligation and suture material, I should like to record that during the past few months I have performed nearly 150 general surgical operations using Coats's No 24 black cotton for every purpose except for uniting mucous surfaces For suturing the peritoneum a strand of cotton has been used doubled and inserted as a continuous stitch, but in all other situations intermittent single-thickness sutures were employed The cotton, which costs 6½*d* a reel, is wound in a single layer (I think this is important) around a piece of rubber drainage-tube and is boiled for 20 minutes It is convenient to clip the loaded rubber tube to the towels near the wound so that a continuous supply of ligature material is at hand The assistant must be instructed to cut the ligature much closer than when catgut is employed In all cases I have dusted the parts concerned in the cotton with sulphanilamide-allantoin powder (Genatosan) No case of wound infection has yet occurred A small proportion of the operations were for infected conditions—e g, appendicectomy for perforated appendix with peritonitis, Thorek's cholecystectomy for empyema of the gall-bladder

Harley Street W 1   HAMILTON BAILEY.

*_** Messrs Allen and Hanburys Ltd suggest that Professor Pannett's article may give the impression that sterilised surgical catgut is difficult to obtain They assure us that the eight firms licensed by the Ministry of Health to manufacture sterilised catgut in this country will be able to meet future demands in both home and export markets, though difficulty may be encountered in obtaining supplies of some brands —ED L

DANGERS OF DULCIN

SIR,—Since official benediction seems to have been given to the use of dulcin as a sweetening agent by the authorisation of the sale of standard amounts in tablets to the public, and since the Extra Pharmacopœia (Vol I p 901) says merely that it is " stated to be innocuous," it seems important to call attention to two articles which, as far as I know, have not been contradicted

Dulcin is *p*-phenetylcarbamide and is allied to phenacetin, being derived from *p*-amidophenol or its ethyl ether *p*-phenetidin both of which according to W A Uglow (*Arch Hyg Berl* 1925, **95** 89) are toxic, causing hæmoglobinæmia cyanosis, sweating and nephritis Uglow says that the use of dulcin started in Russia in 1917, and he quotes a report by Prof A A Lichatschoff that dulcin is partly broken down in the body to *p*-amidophenol so that it should be used only in small doses and by healthy people A year later it appeared again in Russia, but was rejected by a committee after experimental investigations, it was found that cooking of faintly acid, neutral or basic solutions led to the formation of *p*-amidophenol Uglow summarises the rather contradictory findings of other observers, and he *concludes that dulcin acts as a blood poison, and that* its use as a sugar-substitute should be forbidden

In the second article Rost and Braun (*Z angew Chem* 1918, **31** 180) say that dulcin is toxic in large doses, especially to young animals, *p*-amidophenol being liberated They say that amounts up to 0 5 g (corresponding to about 125 g of sugar), spread out over the day may be regarded as harmless to humans They quote a fatal case in a child who took 8–10 g, while another child who took less became seriously ill

The specimen of dulcin I examined was much less sweet than saccharin, and a good deal less than is usually claimed for the substance, so there seems a possibility of the safe dosage being exceeded I note, too, that the report of the Campden Research Station recommends the use of dulcin for sweetening canned fruits, as being "probably less toxic than saccharin " In the process of autoclaving these the state of affairs the Russians found dangerous—cooking in faintly acid, neutral or basic solutions—might be reproduced

Hayward's Heath J W SHACKLE

INTRAMEDULLARY TRANSFUSION

SIR —Your annotation of June 27 (p 769) concerning American reports on intramedullary transfusion prompts us to record our own recent experiences in this field

During the past few weeks we have performed eight transfusions via the sternum on adult patients suffering from the following conditions leukæmia (1), aplastic anæmia (3), hæmophilia (2) and hæmatemesis (2) The technique of introducing the needle into the sternum was identical with that which we have been accustomed to employ in sternal punctures for diagnostic or research purposes After infiltration of the skin, subcutaneous tissue and periosteum with a local anæsthetic, an ordinary Salah sternal-puncture needle is introduced in a perpendicular or slightly inclined plane into the sternal cavity, at about the level of the upper border of the third rib The stylet of the needle is withdrawn, a 'Record' syringe attached to the needle and a small quantity of marrow juice is aspirated The syringe is then removed and the adaptor of the transfusion apparatus, previously set up, is forthwith connected to the needle and the transfusion proceeded with

We have not found preliminary washing out with saline necessary Whole citrated blood was used, and the reservoir suspended at a height of 3–4 feet above the patient's chest The control clamp was opened to its full extent, the rate of flow being governed by the ability of the contents of the medullary cavity to absorb the blood In our cases the rate varied from 50–150 drops per minute, being on the average approximately 120 The amount of blood transfused at one session ranged from 1 to 3 pints In no instance was any difficulty or untoward result noted, nor was any discomfort complained of We observed that, on completion of the transfusion, removal of the adaptor was followed by a reflux of blood through the needle After withdrawing the needle however and strapping a pad over the puncture wound no trouble with bleeding was encountered Strict sterility is obviously called for Our has been to cover the area around the needle wi sterile towels No support for the needle has found necessary as it stands firmly in the cortex bone

Our experience, admittedly so far very limited, confirms the claims made for the simplicity, conv and safety of this method of blood-transfusion method should also clearly be of value for saline and other fluids While it is probable occasional pathological conditions may render sternal cavity relatively impermeable, in the majority of cases the adoption of this technique render cutting down on veins unnecessary As observe in your annotation, the method should of particular value in obese or shocked patients collapsed veins

RUSSIAN-ENGLISH TECHNICAL DICTIONAR

SIR,—There is an urgent demand for an up Russian-English dictionary of scientific and *terms A number of Russian-English glossaries* specific terms have been compiled by various sci institutions and individuals, and it would be extremely helpful to scientists and technical translators if copies of these glossaries could be collected together and placed in the Science Library in London where one complete set could be consulted Will, therefore, any insti or individual who has compiled a glossary of R scientific or technical terms, whether printed or m please sent a copy to the secretary, Anglo-Soviet Sci Collaboration Subcommittee, The British Council, Hanover Street, W 1, who will collect these for Science Library It is hoped later to compile a dictionary, but the immediate aim is to collect different glossaries in one place where they can be sulted Each glossary will be known by the name its compiler

E J RUSSELL,
Chairman, Anglo Soviet Scien
Collaboration Subcommittee

CHALK IN BREAD

SIR,—In his letter of June 27 Mr Bacharach accuses me of " ignorance, unpardonable in a public man, or wilful distortion," because I implied " that the calcification of bread has been adopted on the unsupported advice of non-medical biochemists " I submit, Sir, that this is a precisely accurate description of the genesis of the proposal to add calcium to bread This is made entirely clear in a Parliamentary answer to me of Feb 12, 1942 (I gave the reference in my letter to you of June 13t The Parliamentary Secretary stated that the " scientific advisers," upon whose advice the Ministry had acted in the " fortification " [including calcification (E G L.)] of bread, were Professor Drummond, appointed in February, and Dr T Moran, appointed in June, 1940 The decision to add calcium was announced in a debate in the House of Commons on July 18, 1940 The present decision, as another recent Parliamentary answer indicates, is a mere fulfilment of that undertaking Lord Horder was not appointed as adviser to the Minister until 1941 and could not be concerned with the decision announced in July, 1940. It is to be noted that the calcium was then to be added to *white* bread and that the phytic acid bogy was an after-thought—a full year after! grand old man of chemistry, Sir Wyndham Dunstan, writing in the *Times* of Jan 20, 1942, voiced a prot similar to mine, against the neglect by the Ministry Food of consultation with the medical profession referring to the " tergiversations of the Ministry of F which if brought together would surely be with parallel in the record of any Government department, he added " it would be to the public advantage if three four physicians of eminence were selected to advise t Minister before decisions are taken on questions invol the public health "

More important considerations are raised in the lead in your issue of July 4, which seems to indicate that th is a positive " danger " to the community in the sumption of bread made of high extraction flour, dan proportionate to the degree of extraction If ement has any scientific sanction—and it surely flicts with immemorial human experience—the nger" cannot be limited to war-time, but must hibit any future general consumption of bread sing the whole grain I would commend to your ice the comments on this subject by the late Sir lliam Bragg, then president of the Royal Society, in *Times* of Oct 26, 1940, occasioned by the Govern- nt's proposals of the previous July for "fortification" bread After a caustic reference to " fads that have no nt but novelty." and pointing out that when whole- al bread formed one of the principal items of diet the trition of nations so fed was superior to that now vailing, and after an eloquent plea for restoration of olemeal, he said

> Science is built on the accumulation of experiences, and ery scientist knows that he must not base his conclusions ly on the last few experiments in the laboratory He must ke into account all that has been done before History is him a very real thing tradition is priceless, because there no substitute for it Practice is based on the experiments innumerable years, and even when there are no written ords to be consulted, the behaviour of men, the thoughts ey have turned over and sifted, the knowledge they have ined in ages of trial and error are all of value they are not be thrown aside in favour of the last galvanometer reading "

House of Commons E GRAHAM-LITTLE

ESTIMATION OF SULPHONAMIDES IN THE BLOOD

SIR,—In his letter in your issue of June 6 (*p* 694) Mr S Hawkins suggests the production of a Lovibond nparator disc for the estimation of sulphonamides the blood, using the method of James May we, as e makers of these instruments, be allowed to say at there are already available three different discs these estimations, using three different methods ? ie first issued in 1939, employs Proom's modification Fuller's method (*Lancet* 1938 i, 260), with sodium hydrogen phosphate and dimethyl-α-naphthylamine ie second disc, issued in 1940, employs Bratton d Marshall's method (N-(1-naphthyl) ethylenediamine hydrochloride) while the third follows Werner's chnique (*Ibid* 1939, i, 18) with *p*-dimethylamino- nzaldehyde In all three cases it has been established at the more usual sulphonamide derivatives may be timated with these discs by the use of a suitable nversion factor, as discussed in the explanatory erature These alternatives seem to cover all normal quirements but if at any time it is shown that a new ethod has outstanding advantages we shall be pleased investigate with a view to producing a further andard disc

Milford Salisbury TINTOMETER LTD

Public Health

Smallpox Imported at Glasgow

THE story of an imported case of virulent smallpox into is country can now be told more fully A ship from ombay arrived in the Clyde on May 29 when an electrical igineer was found to be suffering from smallpox and as transferred to Robroyston Hospital where he died n June 2 He had sickened on May 21/22, the rash ppearing two days later and becoming confluent All rsons on board the ship were examined and re- ccinated, passengers being allowed to proceed to their stinations where the regional MOH was informed n June 5 an engineer was found at the daily crew spection to be febrile with swelling of the arm and local lenitis associated with severe vaccinal reaction On ie 7th he was removed to hospital when a few macules ere observed on the skin of the upper chest Further acules appeared and matured and although after the itial febrile attack he was not ill in himself he was garded as a case of modified smallpox Several other embers of the crew were removed on suspicion, some these also were regarded later as cases of modified nallpox

In the early hours of June 10 an assistant cook who id no obvious direct association with the original case as removed to hospital with a morbilliform eruption, the diagnosis being at first complicated by his having taken a large number of sulphapyridine tablets By midday, however, papules were showing and he died of confluent smallpox on the 15th He had been successfully vaccinated on May 29 On June 11, one of the departmental MOs dealing with the cases fell ill of smallpox He had been twice revaccinated without taking and had some degree of protection from previous vaccination On June 21 another member of the crew whose vaccination did not take on May 29 but did on June 11 developed a very modified attack

Two passengers are known to have become affected One was a Polish pilot officer who had been vaccinated in infancy, at 7 years and 21 years, and again on May 29 His attack amounted only to a few papules The other was a baby who fell ill while under observation at Swindon, where there were two further cases This appears to mark the end of the " ship phase " of the outbreak, the total cases involved being eleven Eight were modified very considerably, and six of them were so modified that the diagnosis was extremely difficult, depending upon careful observation of the evolution of the lesions

Between June 22 and 26 sixteen cases were reported among the general population in widely separated parts of the city away from the dock area 2, 5 4, 3, 2 on successive days They must have arisen from a source of infection which existed between June 10 and 14 but inquiry failed to reveal any connexion with the ship. or with the hundreds of ship contacts who were vaccinated and kept under daily surveillance The disease when fully developed was typical Asiatic smallpox Two of the cases were hæmorrhagic, one of them fatal In all by July 6 there had been four deaths Four of the cases were aged 10–15, the numbers in successive older decades being 2, 2, 4, 1, 0, 3

Energetic measures were taken by the Glasgow public health authority to cast a wide net of vaccination around each case and supervise contacts On June 29 it was decided to advise and offer general revaccination to the population of the city, 24 centres were opened on July 1 and 40,000 persons vaccinated on the first day A state of epidemic was declared in the district of the port of Glasgow by notice in the *Edinburgh Gazette* dated July 3

Sir Alexander Macgregor remarks that the two points of special interest about the outbreak are

(1) The occurrence among the ship's crew and passengers of cases complicated by vaccinal reactions and modified almost beyond recognition, side by side with a confluent case where vaccination was apparently not early enough to afford protection

(2) the spread of the disease in the general population with no obvious connecting link with the ship

Infectious Disease in England and Wales

WEEK ENDED JUNE 27

Notifications—The following cases of infectious disease were notified during the week smallpox, 2 (at Swindon), scarlet fever, 1320 whooping-cough, 1394 diphtheria 719, paratyphoid, 8, typhoid, 6, measles (excluding rubella), 6375, pneumonia (primary or influenzal) 655, puerperal pyrexia, 188, cerebrospinal fever, 108, poliomyelitis, 12, polio-encephalitis, 1, encephalitis lethargica, 6, dysentery, 151, ophthalmia neonatorum, 94 No case of cholera, plague or typhus fever was notified during the week

Deaths—In 126 great towns there was no death from scarlet fever, 1 (0) from an enteric fever, 7 (1) from *measles*, 8 (0) from whooping-cough, 11 (0) from diphtheria, 31 (6) from diarrhœa and enteritis under two years, and 6 (0) from influenza The figures in parentheses are those for London itself

Hull reported the death from an enteric fever. Halifax Liverpool and Birmingham each reported 3 deaths from diarrhœa

The number of stillbirths notified during the week was 235 (corresponding to a rate of 38 per thousand total births), including 17 in London

---

BRITISH HOSPITALS ASSOCIATION—This association has in the current year increased its membership by 106 hospitals and 35 convalescent homes and homes for incurables The total number of constituent institutions is now 985

MEDICINE AND THE LAW

Cancer Act Prosecution

Walter Sharples, of little Bispham near Blackpool, was prosecuted at Fleetwood lately for having inserted in a newspaper the following advertisement "I am willing to give my services free to those suffering from cancer on the tongue, and I guarantee a cure within 48 hours, providing it is in its early stages" The Cancer Act, 1939, forbids the advertisement of offers to treat persons for cancer or to give advice in connexion with such treatment Mr Sharples, who pleaded guilty, said he was under the impression that he was doing nothing wrong, he was fined 20*s* Two defendants who published the newspaper were fined £2 10*s* each, it was said on their behalf that the advertisement was inadvertently accepted The deputy clerk to the Lancashire county council, who prosecuted, told the magistrates that this was the first prosecution of its kind in Lancashire and the North of England, possibly the first in the whole country Two years ago, however[1] the Bath magistrates bound over a herbalist for displaying in a shop window a claim to cure cancer "We think you did not know about the statute," said the chairman of the bench, adding rather surprisingly "we did not know about it ourselves" But the purpose of the law is clear The exploitation of fears and hopes is a scandal of which Parliament took belated notice There have been three stages in the restriction of undesirable advertisements of remedies—the Venereal Disease Act in 1917, the Cancer Act in 1939, and the Pharmacy and Medicines Act, dealing with Bright's disease, diabetes, epilepsy, paralysis, tuberculosis and certain other named diseases, in 1941 The legislature seems to have treated such advertisements more tenderly since the last war The 1917 act contemplated trial on indictment with a maximum penalty of two years imprisonment, in summary proceedings before magistrates there might be a fine of £100 or a sentence of 6 months' imprisonment The 1939 and 1941 acts contemplate summary proceedings only, the maximum punishment for a first offence is a fine of £50, for a second offence the penalty may be £100 fine or 3 months' imprisonment or both The two later acts contain safeguards and statutory defences which were not provided in 1917, moreover no prosecution under them can occur without the consent of the Attorney General and Solicitor General Treatment for venereal disease creates possible opportunities for blackmail, otherwise it is hard to see why the legislature should have become less firm in suppressing the cruelty which these offences inflict Prosecution, even if the resultant sentences are slight, may give a needed publicity to the statutory prohibition We must hope, too, that a more general knowledge of the elementary laws of health will destroy the appeal of a promise to cure cancer within two days

---

[1] *Lancet*, 1940, i, 708

HOME FRONT CASUALTIES —At 2 30 P M on Thursday, July 16, at the London School of Hygiene, Keppel Street, W C 1, Prof M Greenwood, F R S, will give a public lecture on civilian hazard of life in this war and in the last

DIPHTHERIA FILM —In future applications from local authorities and MOH's for hire of the film "Defeat Diphtheria" should be addressed to the Central Film Library, Imperial Institute, South Kensington, London, S W 7 There are 25 copies of this sound film in 16 mm size (non inflammable) and 4 in 35 mm size (inflammable) and applications to borrow it should be made at least two weeks in advance, specifying the size required and the make of sound projector with which it will be shown No attempt should be made to get this film shown in public cinemas during ordinary performances as this would be a breach of an agreement made with the Cinematograph Exhibitors Association. Arrangements may, however, be made for showing it in cinemas outside ordinary performance hours, and of course at other places, provided that no admission fee is charged If it is desired that the film should be shown by the Ministry of Information's mobile film unit application should be made to the film officer attached to the Ministry's regional headquarters A silent version of the film is in production

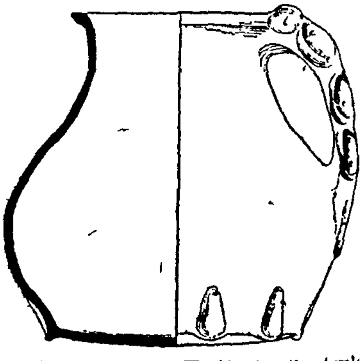
Notes and News

A MEDIEVAL JUG AND ITS CONT

G C DUNNING, BSC, FSA

HANDLED jugs are often found in excav medieval sites and this in itself is an indication indispensable place occupied by these vessels in household of the Middle Ages A great deal co the uses of jugs and other pots may be learnt illustrated manuscripts, and is more informative varied than the evidence obtained from excav These sources show that jugs were commonly drawing water from the courtyard well, in drawing from casks and storing it in the cellar cupboards, were in frequent use to serve wine at the table

A different purpose is evident for a jug in the H Museum, and I am indebted to Mr H C Andrews, the curator, for permission to publish this account of it (see figure) The jug was found about 1903 on the site of the Green Dragon Inn at Hertford It is of unglazed grey ware, 6¾ in high and 7 in in body diameter, of squat globular shape, and the handle is marked down the sides by large thumb impressions It ha sagging base usual to medieval jugs, and the ed thumbed down at intervals to render it more a feature not known earlier than the thirteenth The jug is most probably of the period 1250–1300



Medieval jug from Hertford (¼ natural

The inside surface of the jug is covered with a buff incrustation, thick and granular on the body vessel, thinner and smooth towards the narrow Mr E M Jope, of the Nuffield Department of chemistry, Oxford, reports on the incrustation as fo

> The pale buff amorphous deposit shows no definite cr line forms on microscopic examination, and consists n of sodium urate, which is at times deposited from acid u usually adsorbing much urinary pigment on the surface particles as it settles On analysis the deposit prov contain a high percentage of nitrogen, and it ans slightly but definitely to the murexide test for uric aci solution of the deposit in dilute hydrochloric acid g yellow-green fluorescence and a spectrum absorption ba the region of 500 mμ, both characteristic of excreted pig resulting from the normal physiological breakdown of pigment This is a striking illustration of the stabil these pigments, and points to the urinary origin of the No chlorides or phosphates could be detected and alt concentration of these in the urine may be depres certain pathological conditions, such as high fever finding taken in conjunction with the presence of sodium and the urobilinoid pigment, which indicate that no he been applied, gives a fairly adequate proof that it is a deposit and not the medieval "sal urinæ," and t resulted from the evaporation to dryness of the contained in the jug

From Mr Jope's report it might be concluded the vessel had been in use for some time simply urinal, but urinals were not introduced until much It is more likely that the jug was used for storing the drinking of which was highly recommended Middle Ages as a remedy for plague and various ail

POSTURE IN INDUSTRY

AT a meeting of the Association of Industrial M Officers held in London on April 25, Dr H A professor of anatomy at Cambridge, spoke on post industry, and dealt first with the development human spine In intrauterine life there is one only At twelve months of age the cervical led Later, as the child walks, the sacral part of the y curve develops The upper part of the spine is icerned with rotatory movement, and the lumbar with xion In old age, both the power of rotation of the per segments and the power of flexion in the lower gments are gradually lost There are four elements in e maintenance of posture (1) proprioceptive impulses om muscles, tendons and joints, (2) semicircular-canal ipulses, (3) evidence of the visual fields, and (4) ctile sensations, especially from the soles of the feet ie sum total of these four gives the information to the ain which is necessary for the determination of posture fact, posture might be described as the neuromuscular echanism by which man keeps himself right-side-up ith the world, so that the world will appear right-side-up him. If the influence of each or any of the four factors absent then the steadiness or maintenance of position ill be uncertain As an example, it may be important keep the feet warm and to use footwear to which one is customed when one is in a position where the tactile nse of the feet is important in maintaining position

Professor Harris next discussed certain critical moveients whose integrity is important if the body is to inction as a satisfactory machine. These are as illows

1 Rotation of the head, which is controlled by muscles ipplied by the cervical nerves and the spinal accessory nerve

2 Abduction of the eyeball, here the muscles responsible e the lateral recti (6th cranial nerve)

3 Abduction of the vocal cords for phonation, activated y the laryngeal branch of the vagus

4 Supination of the forearm, this is controlled by branches the musculocutaneous nerve, the fibres being derived from ie 6th and 7th cervical segments

5 Abduction and adduction of the fingers, controlled by ie deep branch of the ulnar nerve (C8, T1)

6 Opposition of the thumb, activated by the median nerve hich contains fibres from the 6th, 7th and 8th cervical egments

7 Eversion of the foot, which is among the last movements equired during a child's development, depends on the itegrity of the external popliteal nerve, the grave disability hich follows Pott's fracture arises from inability to perform his movement freely

8 The action of the gluteal muscles is important in that hey involve movement of the body forwards from the standng still position, from sitting to walking, and in speeding up of pace, carrying, &c, they are innervated by the gluteal ierves, which contain fibres from the 4th and 5th lumbar and the 1st sacral segments

When any of these critical movements are interfered with one of three nerves is most commonly affected The 6th cranial nerve, the ulnar nerve and the superior gluteal nerve appear to be the most vulnerable to attack by injury or disease The gluteal nerve, which consists of fibres from the 4th lumbar segment, follows a very omplicated course, this may, in part, account for its vulnerability

Professor Harris then referred to the importance of emembering the ages at which certain epiphyses join up, so that the strain of heavy lifting may be avoided at an early age where this would be dangerous He cited the coracoid process to which the biceps muscle is attached and the ossification of the pelvis at puberty as examples In the former case heavy lifting by young boys, and in he latter long periods of standing by young girls, are to be avoided on this account The epiphysis of the oracoid process joins up at 15 years, and the centre of the os innominatum does not attain full bony maturity until 18 years Many accidents are due to the fact that a ramped posture did not allow muscles to respond rapidly when quick movement was needed In conclusion, Professor Harris said he is often asked whether factory work may have a serious effect on women's health Provided certain elementary medical and physiological facts are intelligently applied with regard to their work there is no reason why it should be harmful

SIR ERNEST GRAHAM-LITTLE has been re elected as a representative of the senate upon the court of London University for a further period of five years

SULPHONAMIDE POWDERS —We understand that methods of sterilisation are now being worked out by the manufacturers in coöperation with LCC pathologists

ALLIANCE

AT a reception held by the Anglo-Soviet Medical Committee on June 29 messages were read from medical organisations and doctors in the Soviet Union, including · M Georgi Miteryev, the People's Commissar of Public Health, Surgeon N S Burdenko, Prof S. S. Girgolav and Prof I G Rufanov, chairman and vice-chairmen of the All-Union Association of Surgeons; the Soviet Scientists' Anti-Fascist Committee, and Academicians Lena Stern, N N Burdenko and A D Speranky. Some messages recalled personal contacts with English colleagues and paid tribute to our surgical tradition and to Lister, whom they rank with their own great Pirogov. We can look with equal respect towards the achievements of Russian surgery, in which the All-Union Association of Surgeons justly take pride

University of Glasgow

On June 26 the following degrees were conferred —

M.D —A G Fergusson (with commendation), A R Hunter, and B T Mann (in absentia)

Royal College of Surgeons of England

Election to the Council —On July 2 three fellows were elected to fill the vacancies caused by the retirement of Mr Hey Groves, Professor Grey Turner, and Sir Hugh Lett The result of the poll was as follows —

	Votes
Hugh Cairns (Oxford)	502
G Grey Turner (British Postgraduate Medical School)	495
Sir Hugh Lett (London Hospital)	399
Lambert Rogers (Cardiff)	383
P H Mitchiner (St Thomas's)	342
Sir Harold Gillies (Bart's)	296
L R Broster (Charing Cross)	212
Sir Lancelot Barrington Ward (Gt Ormond Street)	180
C A Pannett (St Mary's)	143

In all 1143 fellows voted, in addition 17 votes were found to be invalid Cairns, Turner, and Lett are all elected for the full period of eight years

Society of Apothecaries of London

The diploma of the society has been granted to the following —

L D Miller, N F Murphy, C J O Taylor J T Wild, G E Barnard, P R Green, M M El Badri, H G King, C Faies, S B Nelles, M Fishman, Pak So and D I Fullerton

University of Dublin

On July 1, at the school of physic, Trinity, the following degrees were conferred

M D—C G Ambrose J E C Cherry, W A Gillespie M A Majekodunmi, Isabella M Murphy and W F Rogers

M B, B Ch, B A O—J M T Adamson J E Adamson, P St G Anderson, Violet K St G Breakey, R B Brenan, Franziska G Brill D M Brooks Helen U Croasdaile, J F Dignan, J B FitzSimons J P Hearne, W J C Hill, E K Holland, A M Jacobson, H H B Lamb, Dorothy W M Last, Margaret E McClelland Joseph McNutt, W B Martin, J J Musgrave, E S Odbert Samuel Potgieter, A W Pringle, R C Rylance, Heinz Schever, K M Shaw, I I Shribman, S B Stein, F S Stewart and W J W Wolfe

Medical Society of London

On Monday, July 13, at 5 P M, Dr Anthony Feiling will deliver his first Lettsomian lecture at 11, Chandos Street, W 1 His subject will be epilepsy and further lectures will be given on July 20 and 27

Medical Honour

The George medal has been awarded to Acting Squadron Leader Robert Hill MB, RAFVR

One night in March two aircraft, carrying bombs, collided on an aerodrome in Malta and burst into flames Shortly afterwards the bombs began to explode and enemy aircraft began to bomb the area Despite the great danger Squadron Leader Hill, helped by another officer and two airmen, successfully extricated four members of the crews from the wreckage Their prompt and gallant action undoubtedly saved the four lives Squadron-Leader Hill has invariably performed exemplary work in dealing with casualties during heavy bombing raids and has set a magnificent example which has done much to maintain a high standard of morale on the station

Priority Milk

The following addition has been made to the list of conditions for which a priority ration of milk may be claimed

Patients with malignant disease, or lymphadenoma or leukæmia undergoing radiotherapy, whether by means of X ray or radium, and who as a reaction to the therapy have difficulty in swallowing or digestive disturbances such as anorexia or vomiting

These patients will be classed 1 (h) in the schedule of diseases and will be entitled to a maximum ration of two pints of milk daily

Royal Society of Medicine

The sections of laryngology and otology will hold their combined summer meeting at the Radcliffe Infirmary, Oxford, on Friday, July 17 At 10 A M, Prof W E Le Gros Clark and Mr C H Hallpike will open a discussion on the central connexions of the eighth nerve Afterwards Prof H W Florey will read a paper on the possible uses of penicillin and Mr R G Macbeth will describe cases of cortical mastoidectomy treated by penicillin irrigations At 2 30 P M, there will be a discussion on fractures of the skull involving the ethmoid and frontal sinuses at which the opening speakers will be Major C A Calvert and Brigadier Hugh Cairns Prof H J Seddon will also speak on regeneration of peripheral nerves

Free Travel for Cancer Patients

At a meeting on June 23 the executive committee of the Cancer Control Organisation for Edinburgh and South East Scotland decided to ask practitioners to make fuller use of the organisation's system of free travel vouchers to enable patients suffering or suspected to be suffering from malignant disease to attend at Edinburgh Royal Infirmary for treatment or examination. The hon. treasurer of the organisation is Prof William Annan, CA, 22 Charlotte Square, Edinburgh

Epsom College

The council have available for orphan daughters o practitioners St Anne's scholarships and Squire scholarships Candidates for the St Anne's must b daughters, fully nine years of age, of medical men been in independent practice in England or Wales fo than five years No such restrictions are laid dow Squire Sprigge scholarships The value of each s is dependent upon the means of the applicant and th and fees of the school selected Forms of applic be obtained from the secretary's office, Epsom Colleg

Scottish Society for Mental Hygiene

The lack of institutional accommodation for ment ives and the treatment of psychoneurosis among me the Services were among the topics discussed on J the annual meeting in Glasgow of the society It w that the prewar inadequacy of institutions for m fectives had become more acute Dr Constance secretary of the association, read a report by Pro Drever, DPhil, on psychological tests in the Ar pointed out that elimination of unsuitable people place at two stages—at the recruiting board, or at tributing depot where the men were first sent All entering the Army were thoroughly examined, me well as physically, and the unfit rejected Dr W M spoke of recent developments in the treatment o neurosis among Service patients, but Dr David contended that there was not nearly enough provis for men discharged from the Army There wa agreement about the importance of preventing u recruits from joining the Army and of doing all possible to restore mental balance before sending m the Services to civil life

---

The fact that goods made of raw materials supply owing to war conditions are advertised paper should not be taken as an indication that necessarily available for export

EPIDEMIOLOGY OF JUVENILE RHEUMATISM *

J N MORRIS, M.A GLASG, M R.C P, D C H
CAPTAIN R.A.M.C, LATE PHYSICIAN TO NOTTINGHAM CITY COUNCIL
RICHARD M. TITMUSS

JUVENILE rheumatism is the least known of the great infectious diseases The cause is obscure, the diagnosis often doubtful and the treatment symptomatic Incidence and mortality are equally uncertain The peculiar natural history of the disease and the lack of adequate statistics make the incidence difficult to estimate For knowledge of the mortality we are largely dependent on the Registrar-General's reports, and they are not directly concerned with rheumatism as a cause of heart disease These aspects of the epidemiology of juvenile rheumatism will be considered in the first part of our paper The immediate infective agent of the disease is still undefined but much information has accumulated on the predisposing factors In America, hereditary influences are increasingly stressed, in this country the malady has long been recognised as one of the group of social diseases Observations are recorded in this paper on some aspects of the social background of the disease which hitherto appear to have escaped attention

RHEUMATIC INFECTION

Several attempts have been made to measure the prevalence of the infection

The Ministry of Health report on acute rheumatism (1927) estimated that 2% of the elementary-school population "in cities and towns require observation on account of manifestations of rheumatic infection" Among insured adults a previous investigation (1924) found that the annual attack-rate for acute and subacute rheumatism was approximately 4 5 per 1000, and that 2 5% of all sickness absence was due to rheumatic conditions Davidson and Duthie (1938) on the basis of a large sample study suggested that the annual rate for the whole population of Scotland was 6 5 per 1000 The disease seems to be declining in severity and commonness (Close 1930, Miller 1937) though Thornton (1938) estimated that in the LCC area the incidence in elementary-school children was still 2 5%

Mortality from rheumatic fever has been falling with temporary interruptions for many years In 1881–90 the rate per million living at all ages was 95, in 1911–20 it was 50, in 1939 it was 25 But rheumatic fever is important only in childhood The trend here has not been so satisfactory At five to ten and ten to fifteen years mortality in 1881–90 was 67 and 103, in 1911–20 the corresponding rates were 62 and 86, and in 1936–38 they were 50 and 60

RHEUMATIC HEART DISEASE

Mortality —Glover (1927) estimated an annual total for England and Wales of 25,000 deaths from rheumatic heart disease Miller (1928) suggested 20,000 Wilkinson in 1935 quoted figures as high as 30,000, as low as 12,000 The difficulty arises because the International List, which is used in vital statistics, classifies deaths from heart disease almost entirely by anatomical lesions, and ætiology is not directly considered (Paul 1930, Hedley 1936) Clinical experience must therefore determine the rheumatic proportion of these deaths, and various series of cases (Grant 1933, Wyckoff and Lingg 1926 and others) are available which indicate the age distribution of the different ætiological types Of Grant's 1000 ex-soldiers with heart disease, the rheumatic group was approximately 80% of the total in the twenties, 65% in the thirties, 28% in the forties and 18% in the fifties In Wyckoff and Lingg's series of New York clinic and private patients about 9% of the cases between fifty and fifty-nine years and 4% of those over sixty years were rheumatic Such percentages could be considered, by analogy, the rheumatic fraction of all cardiac deaths in the decade specified, though there are obvious sources of error in such a method A check is provided by information on the expectation of life in patients with rheumatic heart disease In De Graff and Lingg's adult cases (1935) the average age of death was thirty-three, of Coomb's (1924) English series only 7% reached the age of fifty Hedley (1940) in a large-scale investigation found that more than 50% of the deaths occurred under thirty years and only 3% over sixty In New York (Swift 1940), where practitioners are now requested to specify rheumatism when applicable in deaths from heart disease, 40% of the cases so reported in 1938 were under thirty, 44% between thirty and sixty

In view of the nature of such data, any estimate of mortality from rheumatic heart disease is bound to be rather speculative. We are therefore diffident in criticising the figures mentioned above; but they seem to us too high The clinical evidence available suggests that the mortality was nearer 10,000 in 1938 and 11,000 in 1930 Since the total number of deaths from heart disease under forty-five in these years was 6722 and 7434, the current concept of the age-incidence of juvenile rheumatism must be erroneous if the higher estimates of 25,000 and 30,000 are more correct.

Rheumatism thus now causes about 10% of all deaths from heart disease, and close on 100% of those occurring under forty. Combining rheumatic fever, chorea and rheumatic heart disease, juvenile rheumatism is responsible for approximately 2% of all deaths in England and Wales, and for 10% between five and forty-five, when it is second only in females to phthisis, and follows phthisis and violence in males

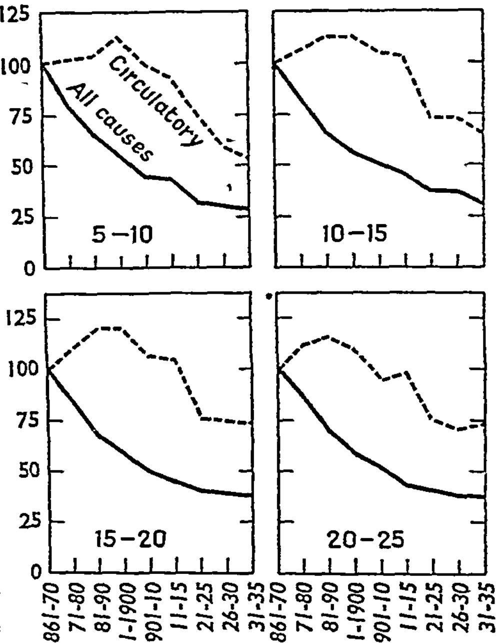

Fig 1
Recent course of mortality from diseases of the circulatory system excluding the war periods the rate for 1861–70 is arbitrarily taken as 100 Male and female rates combined

The total estimates just reached are so hypothetical that to judge mortality trends from a series of such would be pointless Instead we have used all diseases of the circulatory system at five to twenty-five—a crude but adequate index. Fig 1 shows a rather unsatisfactory course up to the 1914–18 war Mortality during the 1920s was however at a considerably lower level In adolescents and young adults the second retardation in the 1920s and 1930s is rather reminiscent of recent experience in phthisis Since 1937 there has been a general improvement

Incidence —Once again we are obliged to piece together scattered bits of evidence

Routine school inspection in recent years (Health of the School Child 1938) has shown that just over 5 children per 1000, or less than 30,000 in all, have organic heart disease In London Thornton (1938) reported the incidence as 2% in 1926 and 0 8% in 1936 In adults it is impossible to state the incidence with any accuracy Among insured workers the report on incapacitating sickness (Edinburgh 1939) showed that under the age of thirty-five the number of new cases of heart disease per annum was about 2 per 1000 in men, just under 3 in single women, and just over 3 in married women In these groups the number ill of heart disease over the whole year was 0 12 per 1000, 0 35 and 0 41 Berkeley, Bonney and MacLeod (1938) indicate that 1–2 5% of all pregnant women have rheumatic heart disease Periodic health examinations are rare in this country. one of us (Morris 1941) found the incidence to be 1% in a sample of 1352 adult males Another source of information is De Graff and Ling's (1935) series where fifteen years was the average between onset of the disease and final heart-failure On the number of adult deaths already estimated, there appear to be 125,000–150,000 cases in England and Wales Paul (1930) in his survey of the whole subject considered the incidence to be approximately 8·4 per 1000

---

* Part of this paper was read at a meeting of the Committee for the Study of Social Medicine

From a consideration of the available evidence it can be hazarded that there are nearly 200,000 cases of rheumatic heart disease at all ages in this country This probably gives juvenile rheumatism the melancholy distinction of being first among all infections as a cause of chronic illness and disablement, chronic, but punctuated with frequent acuter episodes and occurring almost entirely in what should be the most useful years of life.

THE SOCIAL FACTOR

Juvenile rheumatism has long been known to be more prevalent—Glover (1930) suggests 30 times more—among the poor than the well-to-do The British Medical Association committee (Miller 1926) and the Medical Research Council special report (1927), however, agreed with some earlier authorities and suggested that the incidence was more selective, being higher in the artisan class than among the very poor This is an observation of great interest, and has been variously explained by Miller (1934b), Wilkinson (1935) and Poynton (1938) It has, of course, also been disputed—e.g, by Hill (1930), Glover (1934) and in the reports of the Kensington Rheumatism Scheme

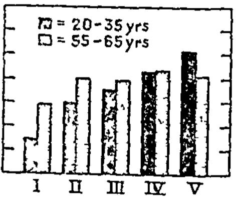

Fig 2—Male mortality ratios (1930–32) from valvular heart disease and chronic endocarditis in different social groups graded from I to V (see text) The rate for all classes is taken as 100 in each age group

In the Occupational Mortality Supplements—those little-worked goldmines—the Registrar-General classifies deaths according to the occupational (and thus social and economic) status of the dead He uses five classes, I, the upper professional and managerial strata, II, the lesser employers, managers and professions; III, the skilled and blackcoated workers, IV, semi-skilled, including agricultural workers, V, unskilled labourers Unfortunately for our purpose here, social class ratios are presented only for age-groups of twenty and upwards Those (1930–32) for rheumatic fever seem to offer some support for the artisan theory, in age-group twenty to thirty-five the ratios are · 108 for classes I and II, 100 for class III, 106 for class IV, and 84 for class V But these will not be further discussed, because rheumatic fever is important only in childhood Several types of heart disease are graded, and chronic endocarditis and valvular disease correspond most closely to the rheumatic group Fig 2 shows a steep rise in mortality with decline in social status, at twenty to thirty-five years the deaths in class V are some 400% of class I.

TABLE I—SOCIAL CLASS MORTALITY RATIOS FOR VALVULAR HEART DISEASE AND CHRONIC ENDOCARDITIS

Males, 20–45 years Standardised, the rate for all males is taken as 100

Social class	1910–12	1921–23	1930–32
	%	%	%
I & II	83	79	72
III	87	92	93
IV & V	119	119	121
Excess of classes IV & V over classes I & II	143	150	168

This diagram represents the closest approximation possible of the social class mortality from rheumatic heart disease In middle age the social gradient flattens, till between fifty-five and sixty-five, when other than rheumatic causes are increasingly common, the class V mortality is not greatly in excess of that for class I Occupational risks in themselves are not important, the

TABLE II—REGIONAL ANALYSIS OF MORTALITY FROM HEART DISEASE IN YOUNG PEOPLE (per 100,000 living)

Region	1931–35 (ages 5–15)	1930–32 (ages 15–25)		Region	1931–35 (ages 5–15)	1930–32 (ages 15–25)

Regions—SE = south east England, excluding London N1 = Northumberland and Durham N2 = Northern rural belt N3 = West Riding N4 = Lancashire and Cheshire M1 = West Midlands M2 = East Midlands E = Eastern Counties SW = South-Western Counties W1 = South Wales, W2 = North and Central Wales Short descriptions all taken from the *Home Market*

ratios for married women are almost the same as those for men The social class gradient is not a new phenomenon calculations based on material in previous supplements permit the comparison for age-group twenty to forty-five seen in table I It may be noted that the excess of classes IV and V over class III has not altered much but their excess over class I has actually risen since 1910–12 There is no evidence here in favour of the artisan's disease theory, in so far as deaths from rheumatic heart disease can be considered an index of juvenile rheumatism the findings are very different

SOCIAL CLIMATE

The death-rates already cited are averages of England and Wales and include urban and rural, industrial and agricultural experience The averages are thus made up from widely differing areas ranging from South West England to the North-East and from Greater London to North and Central Wales. Clearly it is necessary to examine the incidence of juvenile rheumatism in such different settings The study of these—the social geography of England and Wales—was much simplified when, in 1931, the Registrar-General divided the country into 12 major social and economic regions which bear much more relation to the realities of the social structure of the country than the older administrative divisions into counties, boroughs and districts, with their artificial aggregation into North, Midland, South and Wales groups During the 1930s, for example, the South-East, Greater London, the South-West and the East were relatively prosperous with a low average of unemployment South Wales (coal-mining), the North-East (heavy industry) and Lancashire (cotton) were all abnormally depressed with excessive unemployment rates Between these economic extremes were the industrial Midland counties and the largely agricultural regions of North Wales, Westmorland and the North and East Ridings of Yorkshire Such environmental factors can now be observed operating on a large scale and significant local differences need no longer be lost in national averages

TABLE III—REGIONAL ANALYSIS OF MORTALITY FROM RHEUMATIC FEVER, 1926–30 (per 100,000 living)

Age group 5–15 years

Region	Boys	Girls
England and Wales	6 9	8 3
North	6 7	8 1
South	4 9	5 3
Wales	8 6	10 1

In tables II and III the regions have been used to construct rheumatism maps Table II analyses the mortality from heart disease for ages five to twenty-five, the most rheumatic (in our sense) decades, hereafter heart disease in this age-group will be termed "(rheu atic) heart disease" The rates for South-East England, South-West and the Eastern Counties are low, or London and the Midlands about average for the ndustrial North rather high, and for South Wales hroughout in excess of all other regions In 1930 the Registrar-General stopped listing rheumatic fever in his short tables Mortality cannot therefore be analysed by he new regions, table III uses the older groupings and hows again a very high Welsh rate

The regional differences in mortality can be expressed n another way—as percentages of the national figure aken as 100 This is done in fig 3 for girls between ive and fifteen The ratios are also shown for two other ocial indices The range between high and low is greater for (rheumatic) heart disease than for phthisis in young women, or for infantile mortality [1]

The natural climatic factors in themselves seem to be unimportant, as the Registrar-General has pointed out, he climate in South-East and South-West England and n South Wales is very similar Low-lying and wet East England had the best rate of all Stevenson (1919) noted this in the decennial supplement for 1901–10 Discussing mortality from "rheumatic fever and heumatism of the heart" he wrote that the "Fen ounties return low rates, but the idea of any pecial association with damp appears to be given up" he mills of God grind slowly

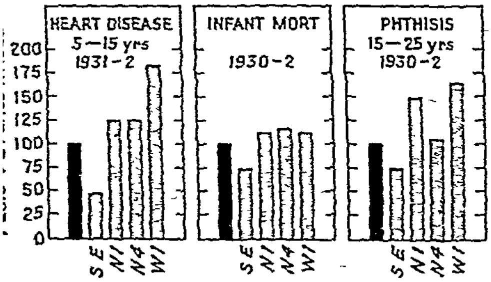

Fig 3 Female mortality from heart disease infantile ailments and phthisis analysed according to regions

In 1901–10 mortality at all ages for "rheumatic fever nd rheumatism of the heart" showed similar trends with high rates in the north of England and in Wales The figures for rheumatic fever in children, 1911–20, likewise closely resemble those found in later years In 1936–39 there was an all-round improvement but the glaring regional disparities remained (see also Young 1921, 1925)

TOWN AND COUNTRY

Since Newsholme (1895) emphasised the influence of urbanisation in juvenile rheumatism this factor has been more or less taken for granted, and relatively little attention has been paid to it Various investigators have found the incidence greater in the town than in the country Fig 4 illustrates the general effect of urbanisation on mortality from rheumatic fever and heart disease n childhood The trend is quite clear in both and the gradation is steady, mortality rises with increasing density of population

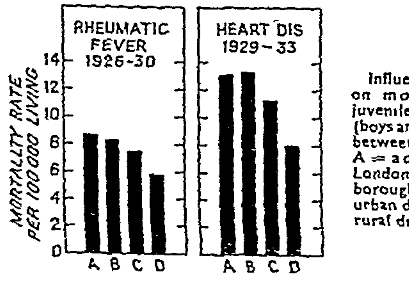

Fig 4 Influence of town life on mortality from juvenile rheumatism (boys and girls combined) between 5 and 15 years A = administrative London B = all county boroughs C = all other urban districts D = all rural districts

The regional break-up of these national figures is once more illuminating Fig 5 shows the mortality-rates for rheumatic fever in boys and girls in the regions used by the Registrar-General before 1931 It can be seen that there is a trend in the expected direction, though it is not very pronounced, in all three divisions Table IV makes the same analysis for heart disease in children, boys and girls combined, in the Registrar-General's social regions (The pattern is identical in young adults, both men and women, but we have presented only the children's table, as internal migration may have complicated the picture at fifteen to twenty-five years.)

TABLE IV

INFLUENCE OF TOWN LIFE REGIONAL ANALYSIS, 1929–33

Mortality from heart disease at 5–15 years per 100,000 living Boys and girls combined

Population density	N1	N2	N3	N4	M1	M2	E	SE *	SW	W1	W2
County boroughs	10 3	14 4	13 8	15 1	12 7	14 5	9 9	11 5	10 4	17 9	
Urban districts	12 5	13 6	11 7	12 5	12 8	13 4	6 9	8 3	7 6	20 1	6 8
Rural districts	11 7	6 5	12 3	9 4	6 5	11	3 9	5 1	4 9	18 8	9 3

* Excluding administrative London

Most of the individual regions show the same unmistakable rise in mortality with increasing urbanisation as was found in all England and Wales, in the North-East and the West Riding the rural rate was about the same as the urban, in Wales it was worse. It is true that the North-East contains some large mining communities anachronistically labelled rural, but in a discussion of density per acre there is no comparing these with the highly urbanised county boroughs such as Newcastle, Sunderland, Leeds, Sheffield or Bradford

When next the factor of urbanisation is kept constant and areas of similar density are compared definite discrepancies are discovered The wide range between the best and worst in all three categories suggests that density of population is not the key factor, and that powerful influences other than urbanisation are operating At each level, the highest rates are found in South Wales and North England But the most interesting feature of this regional layout is that mortality from rheumatic fever was greater in the Welsh rural districts than in the urban areas of the whole country (fig 5) or of the North or South, and in the same way mortality from (rheumatic) heart disease was higher in the villages of South Wales than in all the big towns grouped nationally or regionally We can therefore conclude that whilst urbanisation is an unfavourable influence it is not nearly so decisive as is commonly supposed

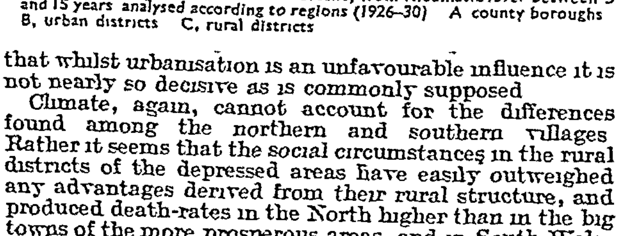

Fig 5—Influence of town life on the mortality from rheumatic fever between 5 and 15 years analysed according to regions (1926–30) A county boroughs B, urban districts C, rural districts

Climate, again, cannot account for the differences found among the northern and southern villages Rather it seems that the social circumstances in the rural districts of the depressed areas have easily outweighed any advantages derived from their rural structure, and produced death-rates in the North higher than in the big towns of the more prosperous areas, and in South Wales higher than in the worst of the big towns In this connexion it may be mentioned that Danischewsky (quoted by Glover 1930), discussing the high incidence of acute rheumatism in Moscow, noted that it was still greater in the agricultural villages around the town

Juvenile rheumatism is not the sole instance where the rôle of urbanisation has been overrated In infantile mortality and tuberculosis of young people, for example, the same distribution holds, and the rural districts of the North and Wales register higher mortalities than the much more densely populated cities of other parts of the country found the incidence to be 1% in a sample of 1352 adult males Another source of information is De Graff and Ling's (1935) series where fifteen years was the average between onset of the disease and final heart-failure On the number of adult deaths already estimated, there appear to be 125,000–150,000 cases in England and Wales Paul (1930) in his survey of the whole subject considered the incidence to be approximately *8•4 per 1000*

---

[1] For a general discussion of regional mortality see Poverty and Population,' by P M Titmuss London 1938

From a consideration of the available evidence it can be hazarded that there are nearly 200,000 cases of rheumatic heart disease at all ages in this country This probably gives juvenile rheumatism the melancholy distinction of being first among all infections as a cause of chronic illness and disablement, chronic, but punctuated with frequent acuter episodes and occurring almost entirely in what should be the most useful years of life.

THE SOCIAL FACTOR

Juvenile rheumatism has long been known to be more prevalent—Glover (1930) suggests 30 times more—among the poor than the well-to-do The British Medical Association committee (Miller 1926) and the Medical Research Council special report (1927), however, agreed with some earlier authorities and suggested that the incidence was more selective, being higher in the artisan class than among the very *poor* This is an observation of great interest, and has been variously explained by Miller (1934b), Wilkinson (1935) and Poynton (1938) It has, of course, also been disputed—e.g., by Hill (1930), Glover (1934) and in the reports of the Kensington Rheumatism Scheme.

This diagram represents the closest approximation possible of the social class mortality from rheumatic heart disease In middle age the social gradient flattens, till between fifty-five and sixty-five, when other than rheumatic causes are increasingly common, the class V mortality is not greatly in excess of that for class I Occupational risks in themselves are not important, the ratios for married women are almost the same as those for men The social class gradient is not a new phenomenon calculations based on material in previous supplements permit the comparison for age-group twenty to forty-five seen in table I It may be noted that the excess of classes IV and V over class III has not altered much but their excess over class I has actually risen since 1910–12 There is no evidence here in favour of the artisan's disease theory, in so far as deaths from rheumatic heart disease can be considered an index of juvenile rheumatism the findings are very different

SOCIAL CLIMATE

The death-rates already cited are averages of England and Wales and include urban and rural, industrial and agricultural experience The averages are thus made up from widely differing areas ranging from South West England to the North-East and from Greater London to North and Central Wales. Clearly it is necessary to examine the incidence of juvenile rheumatism in such different settings The study of these—the social geography of England and Wales—was much simplified when, in 1931, the *Registrar-General* divided the country into 12 major social and economic regions which bear much more relation to the realities of the social structure of the country than the older administrative divisions into counties, boroughs and districts, with their artificial aggregation into North, Midland, South and Wales groups During the 1930s, for example, the South-East, Greater London, the South-West and the East were relatively prosperous with a low average of unemployment South Wales (coal-mining), the North-East (heavy industry) and Lancashire (cotton) were all abnormally depressed with excessive unemployment rates. Between these economic extremes were the industrial Midland counties and the largely agricultural regions of North Wales, Westmorland and the North and East Ridings of Yorkshire Such environmental factors can now be observed operating on a large scale and significant local differences need no longer be lost in national averages

TABLE III—REGIONAL ANALYSIS OF MORTALITY FROM RHEUMATIC FEVER, 1926–30 (per 100,000 living)

Age group 5–15 years

Region	Boys	Girls
England and Wales	6·9	8·3
North	6·7	8·1
South	4·9	6·3
Wales	8·6	10·1

In tables II and III the regions have been used to construct rheumatism maps Table II analyses the mortality from heart disease for ages five to twenty-five, the most rheumatic (in our sense) decades, hereafter heart disease in this age-group will be termed "(rheu-lay almost as important unfavourable rôles in hot as in old climates "

The upshot seems to be that all these factors, damp and crowding, malnutrition and fatigue, lack of sunshine and holidays, inferior medical care, inadequate clothing and leaky boots are responsible—the whole life of the underprivileged child "The destruction of the poor is their poverty" In social medicine such multiple non-specific causation is not unexpected The first stage in this long history may well be a child constitutionally predisposed to rheumatism On the whole question of inheritance there is little substantial evidence In any case, the disease is seen to be so sensitive to social inequality that emphasis on hereditary influences is premature

We have been able to touch on only a few of the problems involved It is still true as in 1927, when Newman wrote, that "no field of preventive medicine offers larger scope for scientific and social investigation than acute rheumatism "

SUMMARY AND CONCLUSIONS

The morbidity and mortality of juvenile rheumatism have been examined with special reference to the social background of the disease

Among infections in this country juvenile rheumatism is probably the greatest cause of sickness and disablement It causes 2% of all deaths in England and Wales, 10% of all between five and forty-five Mortality is declining, though more rapidly in children than young adults Regionally, and in the county boroughs, the death-rate varies widely and rises with the degree of poverty

Mortality on the whole increases with the density of population; this seems to be a function of the greater poverty in the towns The depressed rural districts return rates as high as the worst of the big towns

No evidence was found to suggest that the artisan stratum is particularly prone to the disease Climate seems of little importance Correlation with overcrowding was inconclusive

The facts elucidated strengthen the view that the whole complex of poverty is involved in the production of juvenile rheumatism

We are obliged to Dr J A. Glover and Lieut Colonel M L Rosenheim for their comments on the paper and to Dr Percy Stocks for the 1939 figures

TEMPORARY LENS CHANGES IN DIABETIC COMA

AND OTHER DEHYDRATIONS

R D LAWRENCE, M D ABERD, F R C P

WILFRID OAKLEY
M D CAMB, F R C P

I C BARNES
M B LOND

(Diabetic Department, King's College Hospital)

WE have recently observed that temporary changes in the lens are constantly visible in cases of diabetic coma accompanied by severe dehydration, and have also noticed similar transient changes during dehydration in 2 non-diabetic patients Comparable changes, have been produced experimentally in animals by osmotic disturbances (Duke-Elder 1940)—for instance, the subcutaneous injection of 0 25 g sodium chloride into a frog makes the lens opaque and this opacity rapidly disappears on plunging the frog into water As far as we know, this phenomenon has not been recorded in the human eye except in connexion with the intense dehydration of cholera (Duke-Elder 1940) and nowhere in detail This is not surprising as the treatment of dehydration calls neither for the opinion of an ophthalmologist nor any examination of the eye, other than digital impression of its tension One of us (R D L) noticed these curious eye changes in a case of profound diabetic coma some 10 years ago, but it was not until we have recently made a routine examination of the lens in such cases that we became aware of their frequency Our examinations have consisted merely in direct ophthalmoscopy using a +12 to a + 20 dioptre lens, + 15 usually giving the clearest focus of the opacities So far we have been unable to observe more accurate detail with a slit-lamp, and, with the exception of one case, it has been impossible to assess subjective visual defects in these semiconscious or unconscious patients We have also been unable to obtain the critical cooperation of an expert ophthalmologist in these observations, but this we hope will later be remedied in our own and other cases

The most common change (seen against the red retinal reflex) consists of a wavy gridiron (fig 1) with the lines showing dark against the red background, as if the capsule were wrinkled in folds In some cases, especially in the early phase and during resolution after intravenous saline treatment, no complete pattern has been seen, but only a fine crinkling confined to the periphery (fig 2) or an odd peripheral streak When dehydration has been more severe bolder streaks like water cleavages have been seen (fig 3), and quadrantic patterns (fig 4) showing up darkly against the red retinal reflex and seemingly situated more deeply in the lens In one case only has an opacity complete enough to blot out the retinal reflex been observed, which began at the bottom of the lens and spread upwards (figs 5a and 5b) The changes were not symmetrical in both eyes but were of the same general pattern One case carefully observed by Mr Eric Lyle in 1935 showed a different intensity of pattern at 2-hourly periods of observation in correlation with the degree of dehydration Here the lenses showed linear striation (fig 6a) which became fainter as the dehydration was relieved by intravenous infusion The lens showed only very faint striations 29 hours after admission though small opaque bubbles appeared at the periphery (fig 6b) which persisted until the patient's death 18 hours later

These changes have been observed in 5 out of 6 cases of diabetic coma in the past 3 months—indeed, in all cases that showed severe dehydration The 6th case was complicated by auricular fibrillation and heart-failure and was only slightly dehydrated In all cases the criteria of dehydration were a sunken facies, hæmo-concentration, a systolic blood-pressure under 80 mm Hg and very low eye tension This ocular hypotension was sometimes intense and was measured in similar cases some years ago by Mr G T W Cashell who obtained readings of 5–10 mm Hg (Schiotz method normal 20 mm Hg), figures comparable with the tension after death This shows how intensely the eye suffers in diabetic coma and the amount of water that must be withdrawn from the aqueous, lens and vitreous gel, the last being probably the most concerned in the production of ocular hypotension

MORTALITY IN THE COUNTY BOROUGHS

The death-rates for (rheumatic) heart disease in the county boroughs, then, vary widely To determine what part social factors play in this is not easy In the first place there is no ready-made index which assesses the social status of these towns The levels of unemployment or Poor Law relief are too sensitive to swings of the economic pendulum , Stock's Social Index (1936), which will be used, is not sensitive enough This index is based on the local distribution of the five social classes The proportion in classes IV and V (the male semi-skilled and unskilled workers over 14 years) is taken as a measure of local poverty at the time the returns were made, in 1931 Unfortunately, the allocation to the different classes was based on the normal occupation of the individual when in work No account was taken of unemployment, and consequently the fact that a great number of men and their families had been subjected to a reduction in their standard of living for anything from a few months to many years was not reflected in the social index However, this index is easily the best available In table V the county boroughs are grouped into five grades of diminishing prosperity , group 1 has less than 28% in social classes IV and V, group 5 has over 43% , the remainder are evenly spaced in between The table also shows the death-rates for (rheumatic) heart disease in these county borough groups for the five years 1929–33 The trend is quite clear the rate for the poorest group of towns is considerably worse than for the most prosperous , there is a steady deterioration from grade 1 to grade 5

TABLE V—MORTALITY FROM (RHEUMATIC) HEART DISEASE THE SOCIAL FACTOR IN THE COUNTY BOROUGHS

Mortality from heart disease at 5–25 years per 100,000 living, male and female combined 1929–33

County borough group	No of C B s in group	Proportion per 1000 in social classes IV and V	Death rate from heart disease in young people
1	12	< 283	12 8
2	14	284–333	17 6
3	27	334–383	18 7
4	20	384–433	21 8
5	10	434 +	22 2

OVERCROWDING

The microclimate (Danischewsky's expression) has also been studied Housing is usually implicated in the production of juvenile rheumatism by two factors—damp (e g , Miller 1926) and crowding (e g , Perry and Roberts 1937, Bach et al 1939) On the first of these we have no new observations to offer The degree of overcrowding can be measured both regionally and for the county boroughs from the Ministry of Health Overcrowding Survey The North-East is worst housed by far, being more than twice as crowded as Greater London and four times worse than South Wales Correlation with mortality from juvenile rheumatism is thus not at all close, and is much clearer for infant mortality and the general death-rate in young people The county boroughs were again divided into five groups, according to their degree of crowding Mortality from (rheumatic) heart disease at between five and twenty-five rose steeply from 13 5 per 100,000 living in group 1, with least overcrowding, to 23 2 in group 4, but fell again to 19 5 in group 5—that is, to almost exactly the same rate as in group 3 Again some correlation emerged, but again not a close one These findings may be material to the discussion (MRC Special Report 1927, Wilson 1940) on familial incidence and contagion It is interesting that the reverse was found in phthisis mortality of young people (Hart and Wright 1939) where the correlation with overcrowding was much more obvious than for poverty as such when measured by the Social Index

DISCUSSION

There is general agreement on the broad issue that juvenile rheumatism is intimately related to an unsatisfactory social environment Discussion mostly centres on the view that incidence is not determined by the degree of poverty but is highest in the artisan class, and the existence of some particular poverty factor which is primarily responsible for the disease The approach to these ancient controversies has hitherto been mostly clinical , we have tried the complementary method of statistical analysis which seemed to us more likely to clarify such social medical problems

We have dealt only with mortality statistics for the very good reason that so few others are available , our ignorance of the morbidity of juvenile rheumatism as of many other major disorders is a long-standing complaint which will not be remedied until periodic health examinations of the whole population are instituted Schlesinger (1938) has rightly warned against over-emphasis of the fatal issue in this disease—patients do recover from it, or may lead useful lives in spite of it Mortality does, nevertheless, measure the significance of the condition for the public health, and it sums up the long preceding years of suffering and incapacity The power of the social factor over mortality from juvenile rheumatism seems established, but it may be objected that the findings cannot simply be applied to the related problems of the incidence of the disease This difficulty cannot be fully overcome, but meanwhile analysis of the material suggests that the social factor operates principally by enhancing the infection or lowering resistance to it. The other phase of the disease—the cardiac—does not appear to be so strongly affected neither pregnancy nor occupation, for example, seem to have much influence on the trends which are almost identical for both sexes, for children and young adults Infection dominates the natural history of this disease—the original tonsillitis, the chronic, relapsing, increasingly severe rheumatism itself, the adventitious respiratory catarrhs Throughout, the rôle of the unsatisfactory environment is evident. Coborn (1931) noted that hæmolytic streptococcal throat infections were commoner in the unhygienic living conditions of the poor The class incidence of acute and subacute rheumatism was well illustrated by Still's figures (1927) , and Hedley (1940) suggests that the more severe forms of rheumatic infection are relatively commoner among the very poor Miller (1934a) observed that no rheumatic child living in his own environment is ever free from the danger of relapse , the relationship of respiratory infections with overcrowding need not be discussed The thread of infection that runs through the history suggests that the observations made here on mortality may apply with equal emphasis to the earlier stages of the disease as well

Various field studies—for example, that of the Bristol and Three Counties by Savage in 1931 and the MRC investigation in Glasgow and London in 1927—have analysed poverty in an attempt to discover if any particular constituent was responsible (see also Poynton and Schlesinger 1937) The findings have largely been negative Damp has most persistently been blamed, yet when other conditions are satisfactory, whether in public schools or colonies for mental defectives, there may be little or no rheumatism Dutch experience points in the same direction The specific adverse influence of urbanisation is not proven A low standard of living, wherever it occurs, whether in town or village, increases the death-rate from rheumatic fever and rheumatic heart disease But poverty is neither the result nor even the necessary associate of greater population density, and to say urbanisation when we mean poverty is no help to clear thinking Nor do the effects of industrialisation afford an easy explanation That the fathers of these rheumatic children in the Welsh and northern villages may have been employed at one time or another in the mines cannot directly affect the issue and the smoke-laden atmosphere of our cities does not apply here As to overcrowding, our findings have been even less conclusive The concept of a " rheumatic stratum " (Miller 1926), excluding the well-to-do on the one hand and the very poor on the other, received no confirmation Both regionally and in the big towns mortality was seen to rise with the degree of poverty

Climate in this country has little influence The mortality-rates for South-West England and South Wales have already been compared The cont between the rural districts of the north are eq definite It is interesting that increasing doubt is be cast on the supposed immunity of tropical populati Swift (1940) discusses the recent and very equiv literature on this subject He adds the comment " crowding, poor housing and poor nutrition seem

We have never seen any visible lens changes during he temporary disturbances of focus that occur so often n two different phases of diabetes, whereby the acute nset or exacerbations of diabetes are accompanied by nyopia and the removal of sugar through treatment by ntense hypermetropia up to +8 D. Both these phases ast only 3–10 days and disappear in spite of the persistence of the same metabolic condition that initiated the changes. Such visual changes are almost certainly due to osmotic variations, but the media remain clear.

SUMMARY

Cases of temporary lens opacification occurring in association with the severe dehydration of diabetic coma, and also in 2 cases of severe dehydration from other causes, are described.

These lens changes seem to be directly dependent on dehydration and disappear when it is corrected by saline replacement. The part played by such water changes in the production of permanent diabetic cataracts is thought to be important in acute juvenile forms but of doubtful influence in the cataracts which develop in older diabetics.

MIDDLE MENINGEAL HÆMORRHAGE IN CHILDREN

JOHN P. LANIGAN, F.R.C.S.I.
ASSISTANT SURGEON TO THE NEUROLOGICAL DEPARTMENT, RICHMOND HOSPITAL, DUBLIN

THE following 3 cases of bleeding from the middle meningeal artery are reported because of the absence of initial concussion and because of the long latent period before the onset of symptoms. In each case the injury was apparently trivial and was not associated with amnesia. The case-notes demonstrate the necessity for a close watch on any child whose head has been injured, and gives some indication of the type of case in which compression is likely to develop. In 2 of the cases irritability and vomiting occurred, 6 hours and 2 hours respectively after the accident; these symptoms may be regarded as an "alert."

CASE-HISTORIES

CASE 1.—A boy, aged 13, was admitted to the Richmond Hospital at midnight on Sept. 20, 1940. At 6 P.M. the previous day he had been hit by a ball on the right side of his head. He was slightly dazed but was able to sit on the crossbar of a bicycle while being taken to a nearby hospital, where a small scalp wound was sutured. During the night he was irritable and vomited several times. On admission to the Richmond Hospital, 30 hours after the accident, he was fully conscious and was able to explain about the accident. He did not complain of headache. On Sept. 21 he was irritable, lying curled up, refusing drinks and resenting examination. Radiological examination of the skull was negative. Next day he had incontinence of urine. Lumbar puncture: clear fluid, pressure 100 mm. of water. On the 23rd, 24th and 25th his condition was unaltered except for a lessening of coöperation with the nursing staff. On the 26th he had a dilated right pupil with sluggish light reflex, left hemiparesis and a left Babinski sign. An operation was performed under local anæsthesia and a large extradural hæmatoma was evacuated. Bleeding from the anterior branch of the artery was controlled by diathermy. Next day his pupils were equal but his clinical condition was not improved. The possibility of a further hæmorrhage was considered and the wound was reopened. This secondary operation revealed the dura up to the bone level, and no fresh hæmorrhage. The dura was opened to allow of a small decompression. A left temporal trephine, performed at the same time, was negative and revealed a shrunken brain. On return to the ward he was given an intravenous drip saline. His condition improved rapidly; the following morning he appeared bright and alert and had no neurological signs. On Nov. 30 he was discharged from hospital. His protracted stay was due to a leak of cerebrospinal fluid from his wound. This probably resulted from reopening the wound and necessitated two plastic operations before it finally healed.

Notable points were the late onset of focal signs, incontinence of urine 3 days after the accident, and the normal pressure of the CSF in the presence of an expanding lesion.

CASE 2.—On the evening of June 22, 1941, a boy of 11 received a blow from a stone on the left side of the head which momentarily dazed him. He was admitted to the district hospital for observation. Reports state that he was conscious on admission and only complained of pain in the left ear, which was bleeding; he was otherwise bright and alert and anxious to be allowed home. On the morning of June 24, 36 hours later, he was found unconscious in bed. Details about the mode of onset of coma were not obtainable. At 3 P.M. he was admitted to the Richmond Hospital. He was then unconscious with a right hemiplegia, a bilateral Babinski sign and a complete left third nerve paralysis. The pulse-rate was 150–160 per min. and blood-pressure 110/70 mm. Hg. Radiological examination demonstrated a vertical fracture extending across the left squamous temporal bone on to the parietal bone. At operation a large extradural hæmatoma was evacuated from the left side, and a bleeding posterior branch of the middle meningeal artery was controlled by diathermy. The dura was seen to be stripped off the bone almost to the middle line, backwards under the parietal bone and to the sphenoidal ridge in front. The wound was closed with drainage leaving this huge cavity between the dura and the bone. On the 25th at 8.10 A.M. he died without regaining consciousness. His fluid intake had been maintained by a pint of citrated blood followed by a continuous drip saline of 5% glucose solution. Autopsy revealed a small tentorial pressure cone, but no fresh hæmorrhage or evidence of re-expansion of the brain.

The points to be noted in this case are the importance of constant supervision, and the futility of operating when the patient's brain has been compressed for such a long time.

CASE 3.—On Nov. 12, 1941, a girl of 6 years fell from a moving bus and was momentarily dazed but was able to walk home, a distance of about 1½ miles. On arriving home she complained of a severe headache, became very irritable and vomited several times. On the 14th, at 11 P.M., on admission to the Richmond Hospital, she appeared normal in every respect. Neurological examination was negative. Radiological examination demonstrated a linear fracture of the right squamous temporal bone. On the 16th at midday, her pulse-rate suddenly dropped from 80 to 64 per min., and the bradycardia was accompanied by a severe frontal headache. Examination demonstrated a hard, non-pulsating swelling in the right temporal region which obliterated the contour of the zygoma. No other clinical abnormality was discovered. At this stage the association of a fracture of the temporal bone with a temporal swelling justified the diagnosis of an intracranial hæmorrhage with some sort of safety-valve mechanism. Under bromethol ('Avertin') anæsthesia, supplemented by local infiltration, the right temporal region was explored through a vertical incision. Retraction of the temporal muscle demonstrated that the squamous bone was bulging outwards, allowing a fringe of hæmatoma to protrude through the avulsed suture line. The bone was opened and a large extradural clot with a bleeding anterior branch of the middle meningeal artery was found. The child made an uneventful recovery and was discharged from hospital three weeks after admission.

An interesting feature of this case is the way in which the expanding hæmorrhage by lifting the bone produced a spontaneous decompression.

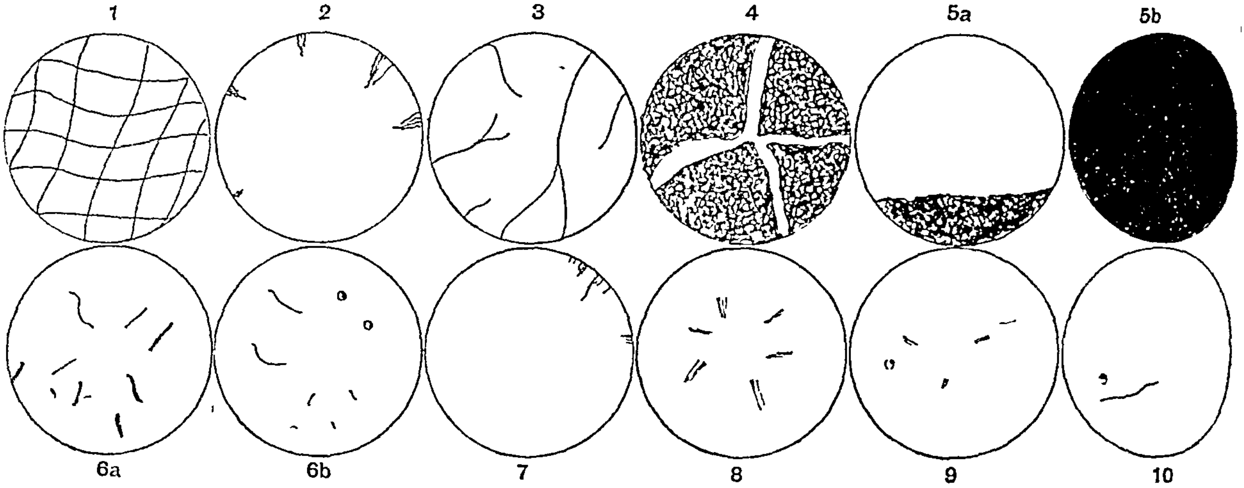
SUMMARY

In three cases of extradural hæmorrhage in children initial concussion and amnesia for the accident were absent in every case. The first sign of an intracranial lesion in 2 of the cases was vomiting with irritability. These phenomena may indicate the onset of compression of the brain in cases in which there has been no concussion. After definite concussion these symptoms usually indicate a step towards recovery.

In the first case incontinence of urine could be regarded as the first focal sign indicating involvement of the frontal lobe; the next sign was a dilated right pupil. In the second case the first focal sign was probably dilatation of the pupil. In the third no focal signs developed.

I am indebted to Mr A. A. McConnell for permission to treat and publish these cases.

LENS CHANGES IN DIABETIC COMA



The duration of the dehydration necessary to produce visible lens changes is not accurately known as it has been impossible to determine how long it had been present before admission In one case of mental degeneration in which the patient was allowed to go into coma by stopping insulin treatment, the changes were first observed 60 hours after the cessation of insulin and 48 hours after onset of symptoms of dehydration, but were by then relatively advanced (fig 5a), 12 hours later the right lens was completely opaque (fig 5b) and the left showed intense cleavages and was semi-opaque

Another patient, a boy of 14, was admitted in diabetic coma with a fair degree of dehydration and moderately low ocular tension On admission, his right lens showed no changes though fine peripheral crinkling was visible in the left lens capsule (fig 7), 5 hours later, after the administration of two litres of intravenous fluid, both lenses appeared normal, 26 hours after admission, however, all symptoms and signs of dehydration having disappeared, streaky black opacities were seen in both eyes (fig 8) which gave the impression of *permanency*, and, *in contrast to the changes first seen*, appeared to be in the substance of the lens rather than in the capsule After a further 4 hours these had almost disappeared, only a few fine etchings being present in both lenses (fig 9), while 3 hours later—33 hours after admission—the right lens was again normal and the left showed only one bubble and one small cleavage line (fig 10) The boy, who was conscious throughout, did not complain of any alteration in sight, and in spite of the presence of the changes depicted in fig 8 could read a book without discomfort

We have observed similar lens changes in 2 non-diabetic patients with severe dehydration, caused in one by the vomiting of intestinal obstruction and in the other by an exacerbation of chronic ulcerative colitis We should expect it to occur in severe diarrhœa and vomiting in infants but have not had the opportunity of examining any such cases

DISCUSSION

We think the basis of these changes is clear, and that their development depends on dehydration and their disappearance on rehydration It is interesting to discuss the phenomenon, especially in relation to the permanent cataracts that develop in diabetics The chemical composition of the lens substance and the processes regulating and stabilising its osmotic composition are not fully understood, but it is certain that the capsule is permeable to diffusible substances such as water, salts and sugar, and that the lens matrix contains free water as well as water fixed to the protein colloids When the blood and subsequently the aqueous is dehydrated, the free water will ultimately diffuse out of the lens so that the lens substance is reduced in bulk and the capsule becomes wrinkled, the earliest and most typical appearance seen Besides this there is probably some opacifying change in the lens fibres themselves to produce such an appearance as seen in figs 4, 5a and 5b These changes are reversible if the water is rapidly replaced and the lens clears up completely But if the water of hydration of the colloids is sufficiently interfered with and the protein coagulated, the process is irreversible and *the opacities are permanent* This process perhaps throws light on the production of diabetic cataracts, which are of two types

Acute cataracts are rare and occur almost entirely in young diabetics They develop rapidly and opacity may become very dense within a few days The lesions are said occasionally to be reversible if treatment is rapid (Joslin 1940) but all those we have seen have been permanent and indeed progressive except in cases of acute dehydration described above Braun (1935), however, describes the complete disappearance of a posterior rosette cataract within 16 days in a boy of 18. We would suggest that these acute cataracts are probably initiated by the type of water disturbance described above, and one of our patients gives a clear history of developing visual defects and cataracts soon after a diabetic coma Yet these acute permanent cataracts are so rare and the occurrence of dehydration so relatively common in the juvenile cases that a higher incidence would be expected if hydration were the only factor involved

Whether the same factor operates in producing the common and slow opacities in elderly diabetics is doubtful Indeed although it has been generally accepted that cataracts are commoner and occur at an earlier age in elderly diabetics than normals, even this is uncertain Waite and Bentham (1935) found the incidence of senile cataracts no greater in 2000 diabetics than in non-diabetics of comparable age-groups and others have come to the same conclusion (Braun 1935) It is therefore uncertain whether the majority of such cataracts are in any direct way connected with the diabetes

Duke-Elder (1940) in discussing the ætiology of diabetic cataracts mentions eight possible factors and appears to think the "hydration of the lens by osmotic influences" the most weighty, but describes a mechanism the exact opposite to that expressed in this paper He argues that, *at least in less severe grades of diabetes*, there is such a loss of salts in the urine that ultimately the aqueous becomes hypotonic and actually gives water into the lens "The lowered osmotic pressure of the aqueous thus determines the inflow of water into the lens, causing, first its deformation and myopia, and eventually the œdema and hydration which results in cataract" We cannot agree with this view and would point out that whenever the diabetes is bad enough to cause thirst tissue dehydration is always present and water will at first be withdrawn from the lens if it suffers any osmotic change at all At other times when the diabetes improves the lens will be rehydrated, and, as years go on, the vicissitudes of the diabetic condition will be accompanied by brief phases of dehydration, rehydration and even occasional superhydration Such changes must cause instability of hydration with possible disturbances of nutrition and structure leading opacification

SULPHANILAMIDE IN TREATMENT OF SMALLPOX

REVIEW OF 103 CASES

P B WILKINSON, M B LOND , M R C P
ATE MEDICAL OFFICER IN THE COLONIAL SERVICE AT HONG KONG,
AND ACTING PROFESSOR OF MEDICINE IN THE UNIVERSITY

FROM November, 1937, to July 1938, Hong-Kong xperienced the most severe epidemic of smallpox in its istory - Approximately 2000 people died of the disease uring this epidemic, which was characterised by a high ercentage of toxic cases Of the 810 victims of the isease admitted to hospital, 83, or just over 10% of the otal series, were suffering from the toxic form

Before attempting to assess the value of a drug or a ine *of treatment it is necessary to know the natural* istory of the disease being treated Smallpox is a clear-ut example of a diphasic disease, the two phases being he toxic *and the focal phase, and it is unfortunate that* he belief is widely held that the focal lesions are an ssential part of the disease In fact, this is not so They are about as closely related to smallpox proper as is he adenitis seen in the second or third week of scarlet ever to *essential scarlet fever* One has, therefore, in describing the effect of any drug on smallpox, to be at pains to state what type of the disease is being treated and at what stage treatment is begun

The usual course of uncomplicated smallpox left to run ts course untreated is as follows An incubation period of about 12 days is followed by a sudden onset which is usually marked by a rigor or repeated rigors, fever, vomiting, nausea, backache and prostration These symptoms are those of the toxic phase, and if the viru-lence of the causative virus be high all these symptoms are intensified and accompanied by the early appearance of hæmorrhage from the mucosæ and into the skin In the severest cases of toxic smallpox these hæmorrhages dominate the clinical picture As a rule, such patients reach hospital before focal lesions have had time to appear, and as death in this type of the disease usually occurs on or about the 6th day many patients die without showing focal lesions The severity of the disease actually seems to retard the appearance of the focal lesions In the less severe cases the symptoms of the toxic phase begin to abate about the third or fourth day from onset, and this alleviation of symptoms is accompanied by a fall in the fever and the appearance of the exanthem and enanthem, the focal lesions, characteristic of the focal phase of the disease These lesions pass through a regular sequence—macule, papule, vesicle and pustule—and are mature about 8–10 days from the beginning of the focal phase At this stage of the disease the patient often falls a ready prey to secondary septic infections, such as cellulitis, muscle abscess and extensive skin sloughing

One more point must be emphasised it is useless to try to gauge the effect of a remedy on the focal lesions unless the vaccinal history of the patient has been established beyond a peradventure Vaccination exerts such a profound *and long-lasting* effect on both the number and type of the lesions that I have thought it wiser to exclude the vaccinated patients in this group from those in whom the influence of sulphanilamide on the lesions was being observed It must be remembered that vaccinal modification influences the course of the disease in at least three ways—it greatly alters the course of the toxic phase , it lessens the total number of skin lesions , and it shortens and changes the natural maturation of these lesions These three effects of vaccination die out at very different rates, the toxæmia-modifying component disappearing first, the number-modifying component *next and the* type-modifying component last This is why toxic smallpox not uncommonly kills patients who have 6–8 well-foveated vaccinal scars, and it also explains those curious cases *in which an* extremely severe toxic phase is followed by a focal phase producing only 20–30 skin lesions The toxæmia-modifying component of vaccination performed *in* infancy has completely disappeared, let us say by the age of 20 , the patient then develops smallpox and either dies in the toxic phase or survives to show only a few abortive lesions in the focal phase, the other two components still retaining some of their effect These considerations have to be borne in mind both in the prognosis and the treatment of smallpox

The effects of sulphanilamide on both phases of the disease were *observed in a series of* 103 cases Selection, which was at first entirely random, later became specialised to this extent if a patient on admission was *obviously* about to develop some secondary septic complication he tended to be given sulphanilamide because experience rapidly demonstrated that he would probably benefit from the exhibition of the drug

ROUTINE TREATMENT

Sulphanilamide (' Streptocide ' Evans) was given in a dosage of 1 g four-hourly day and night with the necessary modifications for age when children were being treated No loading dose was employed and the drug was invariably given in powder form by mouth It was unnecessary to enforce any special *dietetic* restrictions as the Chinese have the sense to live on a decoction of sugar-cane in water when they are severely stricken with smallpox, and the less severely ill patients could not have obtained eggs and onions had they wanted them Salines were not given to patients receiving the drug. All these patients, save those with toxic smallpox, had their skin lesions painted daily with a saturated solution of potassium permanganate, and their eyes, ears and nostrils treated with 10% ' Argyrol,' glycerin carbolic drops and liquid paraffin respectively, but apart from these no other measures were adopted

RESULTS

Toxic phase —Of the 83 toxic cases in *the whole series* only 2 survived, and both these men belonged to the very small group of toxic cases which has a fighting chance of survival Neither of them had sulphanilamide Of the 13 toxic cases treated with the drug, not one recovered , 10 of them were unvaccinated, 3 showed good vaccinal scars , 12 were admitted *to* hospital *on* or before the sixth day of the disease, the 13th on the seventh On the average these patients were admitted on the fourth day of their illness, and they lived *after* admission for 3½ days on the average One man who had *no* vaccinal scars was exceptional in living for 16 days , he passed out of the toxic phase *and* seemed *likely* to recover, but finally succumbed to the pulmonary œdema which often ends the lives of those toxic patients who linger on

Naturally, *the shortness of the* survival period after admission means that the drug had not long in which to act, but in no case was the natural course of the disease modified in the least by its exhibition, and *it is note-worthy* that the one man in this group *who* lived on for 16 days showed no signs of such modification as a result of treatment It seems, then, judging by this small group of patients, that the drug exerts little if any influence on the toxic phase of the disease

Focal phase, unvaccinated —The remaining 90 patients in this series are divisible into *two* groups—41 who had been vaccinated and 49 who had not The 49 un-vaccinated patients afford reasonable material from which to draw conclusions *about the influence of* sulphanilamide on the focal lesions as they comprised confluent, semi-confluent *and discrete* cases of the disease running an unmodified course In only 19 of these patients was the evolution of the focal lesions changed, the change commonly seen being an arrest of the lesion at the vesicular stage It closely resembled the horn-pock condition so often seen in well-modified smallpox The vesicles, instead of developing into mature pustules, dried up and left the face covered with a multitude of small horny pocks In these 19 cases the secondary focal or septic fever was either annulled or diminished In the remaining 30 cases *in this* group the evolution of the lesions and the course of the disease remained *unaffected*

Focal phase, vaccinated —In this *group of* 41 patients sulphanilamide was used for some septic complication which had arisen during the course of the disease the commonest being boils, muscle abscesses, skin sloughing, cellulitis and otitis media , the rarer ones, panophthalmitis, suppurative arthritis, suppurative periostitis and streptococcal infections of the genito-urinary tract It is in these complications of the focal phase that sulphanilamide proves most useful, and treatment with the drug was not begun in these cases until some septic complica-

INFLUENCE OF THYROTOXICOSIS ON MENSTRUATION

P M G RUSSELL
M B LOND F R C S, M R C O G
SURGEON TO THE EMS, ANTE-NATAL OFFICER TO QUEEN CHARLOTTE'S HOSPITAL

EDNA M DEAN
B SC LOND
LABORATORY TECHNICIAN TO NEW END HOSPITAL

(From the Thyroid Unit, New End (LCC) Hospital, Hampstead)

SCANT attention seems to have been paid to the accurate study of the influence of thyrotoxicosis on menstruation Indeed, misleading views on this subject are common in the standard English textbooks, some of which make the bald statement that thyrotoxicosis tends to produce menorrhagia, whereas in the series of 139 cases analysed below this symptom was present in 2 cases only The cases were all seen at the LCC, Thyroid Unit since its inception in 1932

In general our results correspond closely to those published by Gardiner-Hill and Smith[1, 2] from St Thomas's Hospital The inquiry has been directed towards finding out the effects of thyrotoxicosis on menstruation and the effects of thyroidectomy on the menstrual periods Preliminary attempts were made to classify cases as primary and secondary toxic goitre, but the distinction is not always easy to make and seemed to have no advantages Doubtful and non-toxic cases have been omitted, and so have cases in which other factors were present which might influence menstruation Thus we have not included patients at or near puberty or the menopause, those with a history of recent delivery or abortion, or those who had recently undergone gynæcological operation such as curettage or insertion of radium into the uterus

Grading of cases according to severity makes it easier to appreciate the progressive effects of the disease, and to assess the scope of operation Such grading must of necessity be somewhat elastic, since personal standards vary, but we classified our cases as severe, moderate or mild on the following basis

Severe cases—These, when at complete rest and under treatment with Lugol's iodine, had a persistent tachycardia of 120 per min or over for two days or more after admission The basal metabolic rate (measured by the Benedict Roth method) was +30 or over Severe emaciation, exophthalmos or other toxic signs were present, but the signs and symptoms were not necessarily all present in each case There were 29 cases of this type, with 5 deaths, 2 of which occurred without operation

TABLE I—MENSTRUATION IN 139 CASES OF UNTREATED THYROTOXICOSIS

Group	Menorrhagia	Normal periods	Scanty or irregular periods	Amenorrhœa
Severe	0	8 (27 5%)	4 (14%)	17 (58 5%)
Moderate	2 (3%)	35* (50%)	25 (36%)	8 (11%)
Mild	0	34 (85%)	5 (12 5%)	1 (2 5%)

* One moderate case had menorrhagia before the appearance of the goitre but the periods became normal as the goitre appeared After operation the menorrhagia returned

Moderate cases—Pulse rate (under the same standard conditions) of over 100 and under 120 per min BMR +20 to +30 Moderate toxic symptoms or signs only There were 70 cases in this class with 1 postoperative death

Mild cases—Those not reaching the standards listed above and exhibiting only mild signs or symptoms There were no deaths in 40 cases of this type One case of Riedel's thyroiditis with mild toxic signs is included in this category

The effect of untreated thyrotoxicosis on the periods is summarised in table I

From the figures it seems clear that in mild cases (and probably therefore in the early stages of the disease) there is no effect on the periods, but that as the condition progresses there is an increased tendency towards scanty and irregular periods, and finally more than half the severe cases develop amenorrhœa Often, however, the periods are not in any way affected even in severe thyrotoxicosis These findings agree with those of Joll[3] Menorrhagia is uncommon, its occurrence only in the moderate group suggests that if it does appear it is of only short duration in the natural evolution of the disease, and is probably not a constant accompaniment

Why thyrotoxicosis should cause oligomenorrhœa and amenorrhœa is not certain Whether both conditions are due to some disordered secretion of thyrotropic and gonadotropic hormones of the pituitary has yet to be shown Microscopic study of curettings from the uterus in these patients together with hormone analysis of the blood and urine should give some clue to the extent of activity in the ovaries and pituitary Further research is needed on this problem It did not seem profitable to pursue the study of dysmenorrhœa in these cases, because it seemed no commoner among them than it would be in a similar number of ordinary women

RESULTS OF OPERATION

Accurate notes were available in only 79 cases The possible after effects of operation are

1 No alteration in the periods where these were formerly normal

2 A return to normal after previous disturbance of the cycle—usually only after a latent interval of 3–4 months from the time of operation

3 Abnormal periods of amenorrhœa persisting after operation

4 Periods becoming abnormal after being formerly normal

TABLE II—EFFECT OF THYROIDECTOMY ON MENSTRUATION

Group	Total	Menses			
		Normal throughout	Returned to normal	Abnormality persisted	Became abnormal
Severe	16	7	8	0	1*
Moderate	40	14	20	1	5†
Mild	23	19	2	1	1‡
Total	79	40	30	2	[illegible]

* Developed amenorrhœa
† In 4 periods became irregular and scanty, 1 developed amenorrhœa
‡ Developed menorrhagia

The results in 79 cases are recorded in table II From these relatively small numbers it seems that a woman with scanty or absent periods due to thyrotoxicosis has a 50% chance of her periods returning to normal after operation Occasionally they may be made worse by operation and this is apparently commoner in less severe cases

SUMMARY

Thyrotoxicosis, even when severe, may have no effect on menstruation When it does affect menstruation it tends to produce first scanty periods and then amenorrhœa, which was present in over half the 29 severe cases in a series of 139

Where the periods had become scanty or absent they returned to normal in about half the cases operated on

Menorrhagia is uncommon in thyrotoxicosis and is probably transient when it does appear

We wish to thank the Medical Officer of Health to the LCC for permission to publish this paper, and Dr R H Swindells, medical superintendent of New End Hospital and members of the medical and surgical staff whose cases and notes have been used in preparing this paper

DEHYDRATION OF FOODS —A joint meeting will be held by the Nutrition Society and the Food Group of the Society of Chemical Industry at BMA House, Tavistock Square, London, W C 1, on Saturday, July 25, at 11 A M, when there will be a conference on the dehydration of foods and its effect on their nutritional value, A later meeting, probably at the end of October, will deal with trace elements in nutrition Further particulars of the Nutrition Society may be had from the hon. secretary, Mr Leslie Harris, DSc, Nutritional Laboratory, Milton Road, Cambridge and then a smaller dose, until a total of 26 5 g had been reached

Chatterjee recorded his experience with sulphanilamide ('Sulphonamide-P') in smallpox in March, 1941 Although he treated only 24 cases of confluent and hæmorrhagic smallpox with the drug, he was satisfied that it was useless in the hæmorrhagic cases but effective in modifying the evolution of the lesions and preventing septic complications Chakrabarty and Ghosh also reported isolated cases of the disease successfully treated with sulphanilamide and sulphapyridine later in the year

Chari in 1942 published a detailed description of the results in 97 cases of smallpox treated with sulphapyridine, sulphanilamide and urea sulphazide All types of the disease were represented in his series His fatality-rates were 24 4% in the unvaccinated patients, 3 7% in the vaccinated ones He concluded that a "sulphonamide" does not abort the disease or do away with the pustular stage even if given earlier, that it is a necessary and valuable drug in the pustular stage of the disease, both for lessening the evil effects of sepsis in the acute stage and for preventing the incidence of late septic manifestations, that it lessens mortality and that it minimises the disfigurement incident to the disease" He is also convinced that sulphapyridine is the most useful drug of the group in this disease

This brief review of the published work shows that all observers are agreed on two points first, that the sulphonamides exert no influence on the virus of smallpox, and therefore do nothing to modify the toxic phase of the disease, second, that they are of very great value in the treatment of the septic complications so common in the focal phase Whether they can or cannot abort the evolution of lesions is still a moot point though the consensus of opinion is that they cannot There is also general agreement that the sulphonamides, used in the septic confluent cases and in the septic complications, bring about a reduction of mortality Most observers consider that their use helps in reducing the incidence of septic complications during the focal phase

At the moment, it is safe to say that the sulphonamides may be given with advantage during the focal phase of smallpox, but that they have no influence on the toxic phase

SUMMARY

A review is given of 103 cases of smallpox treated with sulphanilamide by mouth

The drug appears to be without effect on the toxic phase of the disease—that is to say, it has no action on the virus of smallpox

It is capable in a certain number of cases of modifying the skin lesions rather as they are modified by vaccination

It is extremely effective in the treatment of many of the complications associated with the focal phase

There is some evidence that the drug, if given early in the focal phase, may modify the number of the lesions, the incidence of septic complications and the degree of subsequent scarring

The drug reduces the fatality among cases showing septic complications

NATIONAL BIRTHDAY TRUST FUND —At the annual general meeting of the fund Sir Julien Cahn, the chairman, said that though activities had been curtailed by the war they continued to maintain the headquarters at 57, Lower Belgrave Street, providing accommodation for the Queen's Institute of District Nursing and the College of Midwives The analgesics appeal fund had supplied 50 gas and air machines free to hospitals, and 46 at a nominal charge, 36 of these to district nursing associations The fund had also supplied 48 machines to EMS hospitals The human milk bureau at Queen Charlotte's Hospital was now supplying 48 hospitals all over the country

QUALITY OF THE NATIONAL LOAF

G N JENKINS, M SC LPOOL, PH D CAMB

E I McDOUGALL
B SC LOND, A I C

P HERBERT
B A CAMB

(Children's Nutrition Council, Cambridge Branch)

WITH the appearance of the national loaf (85% extraction) on the market and its subsequent establishment as the nation's bread in April of this year, the question of a simple method of checking the quality of flour and bread has taken on added importance The properties to be aimed at in the national wheatmeal flour have been set out in the memoranda of the Medical Research Council[1] It should be of 85% extraction and contain as much as possible of the germ and aleurone layer to supply maximum amounts of the B vitamins and of protein of high biological value, and as little of the bran as possible, this last is the most indigestible and least nutritious part of the wheat and imparts the colour, flavour and texture of "wholemeal" preferred by some but disliked by a large proportion of the population One of the objects of restricting the bran to the minimum and recommending an upper limit for the amount of "crude fibre" appears to be to provide a flour which would still be suitable for those for whom a low residue diet has been prescribed

The ash content has hitherto been widely used as the criterion in milling studies on flour, but it is not satisfactory for application to national flour since the ash contents of the germ, aleurone layer and bran are all high[2] and differ but slightly and they therefore give no information as to whether the flour contains the undesirable bran or the highly nutritious fine weatings and germ, furthermore, it could not be applied to bread The crude fibre content is a better criterion and was used in the small survey described below, the aim of which was to gain some idea of how far the fibre content of the national loaf, as sold, conformed with the recommendation of an upper limit of 0 9%, on a 15% moisture basis, for the national flour

METHOD AND FINDINGS

About twenty samples of the national loaf were obtained from towns widely distributed throughout the country by members of the Association of Scientific Workers and the Children's Nutrition Council and others, to whom we wish to record our thanks It was requested that one thick slice be sent from loaves bought over the counter The samples were received between Feb 15 and March 15 The crust was removed and the crumb air-dried overnight, at room temperature, after which it was ground in a coffee mill three times

Two-gramme samples of the dry breadcrumbs were used for the crude-fibre determinations which were carried out by the method of the American Agricultural Chemists,[3] which is also the method used by the American Association of Cereal Chemists[4] for this type of material This method was checked by determining the crude-fibre content of a few samples not included in the survey by this and by the official method used for feeding-stuffs in this country[5] There was satisfactory agreement between the results of the two methods, in both of which the ether extraction was omitted as unnecessary for bread Each sample was analysed by two workers who each made two estimations The moisture content was determined by heating separate weighed samples for four hours at 110° C, and the crude-fibre results were calculated to a 15% moisture basis for comparison with the values for flour The results are presented in the table

Of the seventeen samples, the values for 10 were within the crude-fibre limit recommended by the Medical Research Council, 5 were slightly above and 2 exceeded it by a large amount These 2 certainly, and the other 5 probably, contained a large percentage of coarse bran at the expense of the more desirable fractions of the tion had appeared Adjuvant measures such as local antiseptic dressings were used once drainage of the muscle abscesses had been established, but there is no question that these cases recovered much more rapidly when treated with sulphanilamide in the way described than when left alone It was the rule, once the necessary local measures had been taken in these cases of boils, muscle abscess and cellulitis, for recovery to be prompt and uninterrupted provided an adequate dosage of sulphanilamide was employed The most dramatic results were seen in the cases complicated by extensive skin sloughing and genito-urinary infections The following cases illustrate the effect of the drug

A Chinese woman, aged 47, suffering from a mild attack of discrete unmodified smallpox She came into hospital when her lesions were vesicular, maturation and crusting followed the normal course and no special treatment was adopted Ten days after admission, when her lesions were still crusted, she had several rigors in the afternoon , for the next two days she continued to have three or four rigors a day, and her fever which had abated rose to 104° F during them There were no obvious signs to account for these rigors and the irregular fever but she finally complained of a "burning and discomfort" on micturition A hæmolytic streptococcus was grown from a catheter specimen of her urine and the exhibition of sulphanilamide brought about a prompt remission of symptoms and an uninterrupted recovery

A Chinese boy aged 9 years, admitted to hospital at the vesicular stage of an unmodified attack of discrete smallpox He was not dangerously ill, and as the disease was running its normal course he was left alone A week after admission his face became œdematous and he complained of giddiness, headache and fever Generalised anasarca developed rapidly, and his urine was reduced to 6 oz in the twenty-four hours and was smoky in colour A clean specimen yielded a growth of hæmolytic streptococci The exhibition of sulphanilamide produced a remission of fever and symptoms within twelve hours, and from then on recovery was uneventful

A Chinese, aged 34, admitted on the sixth day of a severe attack of confluent smallpox He had been variolated by the nasal route when a child of 3 years, and had "taken" At the height of maturation he developed extensive sloughing of the skin over the 4th, 5th and 6th ribs on the posterior aspect of the left hemithorax His secondary fever continued to increase and the skin over the whole of the left flank rapidly became œdematous Sulphanilamide was begun at this stage in the routine dosage and immediately checked the tendency of the sloughs to spread Eventually the man made a complete recovery after 100 days in hospital and a severe complicating attack of beriberi

Whole series —The figures for the three groups are as follows

	Toxic	Focal Phase Unvaccinated	Vaccinated
Cases treated	13	49	41
Deaths	13	11	2
Fatality %	100	22 4	4 8

Of the unvaccinated patients in the second group who died, 2 were women in the puerperium and 6 were young children The 2 deaths in the vaccinated group were due to confluent smallpox The fatality for the whole series during this epidemic was 44%, and there is no doubt that sulphanilamide lowers the mortality in the septic confluent cases and in those cases showing some septic complication but as it is impossible to give the proportion of vaccinated to unvaccinated patients in the whole series it would be unwise to stress the comparison between the treated and untreated groups

DISCUSSION

Certain points can be made from the results obtained in this group of 103 patients First the toxic phase of smallpox is not influenced by sulphanilamide in the dose given, 6 g in the twenty-four hours , second, the focal phase does appear to be modified in a certain number of unvaccinated patients in the sense that the normal evolution of the lesions is arrested at the vesiculo-pustular stage with a resulting diminution or suppression of the secondary or focal fever , third, the septic complications which occur so frequently in the focal phase are profoundly influenced by this drug In treating the common septic complication of this phase sulphanilamide is extremely valuable and on occasion does undoubtedly save life In muscle abscess, cellulitis, sup periostitis, suppurative arthritis, streptococcal infections, otitis media and panophthalmitis it has rapidly, and I think the real value of the drug is in the treatment of these septic complications

More might have been expected from the use of sulphanilamide in the focal phase of unvaccinated cases but these observations tend to show that the drug cannot be relied on to abort or to influence the focal lesions The organisms found in the pus of smallpox are usually either a hæmolytic streptococcus or a staphylococcus and in the majority of these cases where a bacteriological examination was possible a streptococcus was isolated Therefore the drug should have produced an observable effect in more than 19 out of 49 unvaccinated patients but it is a disappointing fact that a number of the unvaccinated confluents showed no response

These findings tally with what we know thus far of the action of the sulphonamide group, and they also agree in the main, with the observations of others who have treated smallpox with the sulphonamides

Buttle, in reviewing the action of the then known members of the sulphonamide group in 1939, pointed out that only two virus diseases—trachoma and lymphogranuloma inguinale—were influenced by them, and it has since become clear that the virus phase of smallpox remains completely unaffected by them The earliest report on their use in the treatment of smallpox seems to be that of King and Rozario in 19 A European woman, aged 33, who had been vaccinated in infancy, was given sulphamidochrysoidin ('Prontosil rubrum') by mouth from the vesicular stage onward, and the drug was thought to have lessened the number of pustules and prevented the secondary fever

In 1940 McCammon treated 4 cases of the disease with sulphanilamide and claimed that 3 of them showed merely an evanescent macular rash, while the fourth developed three pustules only He makes no mention of the vaccinal history of any of these patients, and the conclusion drawn, that sulphanilamide is beneficial if given early in smallpox, does not seem to be entirely justified Fitzgerald Moore, writing in the same year, stressed the need for caution in assessing the results of sulphonamide therapy in smallpox, and mentioned that he had treated 6 confluent cases with sulphanilamide during a Nigerian epidemic with a fatality of 100%

In March, 1940, Pierna described the results he had obtained in two different epidemics which occurred in Spain after the war His report is based on 7 cases only and in most of them sulphanilamide treatment was begun in the vesiculo pustular stage The dosage and route of administration employed are not described, but the drug when "given to subacute, acute and confluent cases produced early improvement in the general condition of the patients, subsidence of fever and cessation of growth of the lesions" The vesicles became converted into attenuated pustules which dried up in 4–5 days, with subsequent shedding of the crusts in another 4–6 days No complications were observed in the cases treated with sulphanilamide, and Pierna concluded that the drug "reduces the period of evolution of the lesions to less than half the normal, that it attenuates the smallpox virus and that it is to be regarded as specific in the treatment of smallpox"

In December, 1940, Patel and Haidu published a valuable review of the results obtained by them in Bombay in the 193 and 1939 epidemics They treated selected cases of the septic confluent type with oral sulphanilamide, 'Uleron' and sulphapyridine, and found that sulphanilamide appeared to be the most effective of the three Uleron seemed to be definitely toxic in the doses they employed and sulphapyridine did not abort the focal phase Further trials were made with sulphanilamide, and between January and May, 1940, 91 cases of semi-confluent smallpox were treated with the drug with 64 controls, and 60 confluent cases with 63 controls These patients were divided into vaccinated and unvaccinated groups, and in both sulphanilamide appeared to bring about a significant drop in mortality The sulphanilamide was given by mouth in a dose of 1 g four hourly for the first week, and in half that dose during the second week Untoward effects were uncommon They concluded that sulphanilamide was the drug of choice for the treatment of smallpox, that it reduced the mortality in confluent cases by about 30%, and that it only seemed to influence septic cases

Early in 1941 Patel also reported the results in 19 confluent cases treated with sulphapyridine The drug given early in the focal phase did not abort the lesions but did seem to avert complications , 5 g daily was given for the first four days

THE LANCET

LONDON SATURDAY, JULY 18, 1942

CIAL FACTORS IN ACUTE RHEUMATISM

THE causa causans of acute rheumatism is known, the rôle of the hæmolytic streptococcus d of the virus are still not clearly defined But, as LE insisted last week, preoccupation with the croscopic organism should not lead to neglect of e "multiple factors" in production of disease It s long been recognised, on clinical grounds, that ute rheumatism is to a large extent a disease of e poorer classes, though it has proved difficult for nical investigation alone to draw any clear-cut nclusions on the relation that poverty was to it e Registrar-General's reports, however, offer aterial for the statistical approach to diseases in ich social factors are believed to play a part As embers of the Committee for the Study of Social edicine, **MORRIS** and **TITMUSS** have investigated the oblem of acute rheumatism by analysing the figures ven in these reports and their deductions will be und on our opening page Poverty as a causative ctor has often been stressed in the past, and attempts ave been made to dissect the responsible components the "complex of poverty" It has been shown at in families removed from poor surroundings the cidence of acute rheumatism is reduced **MORRIS** d **TITMUSS** now show that acute rheumatism and eumatic heart disease must indeed be classed with gh infantile mortality and a high incidence of lmonary tuberculosis as ills bred by poverty

Deaths from acute rheumatic fever are few, but eaths from heart disease in young adult life are any Rheumatism thus ranks with tuberculosis an outstanding cause of invalidism and as one the major killing diseases in this period of life has often been suggested in the past that acute eumatism affected the artisan class more than y other large group in the population, even the ery poor Analysis of mortality from valvular eart disease by social class shows, however, a nsistent rise of mortality with deepening poverty **ORRIS** and **TITMUSS** find no evidence to suggest that e selective incidence of acute rheumatism is influ- nced by any factor apart from those associated with overty As with other social diseases, the mortality om rheumatic heart disease is higher in poverty-ricken areas Roughly speaking it rises with creasing density of population, but the mortality is gnificantly higher in the poverty-stricken villages of outh Wales than in any of the large towns Urbani- tion thus contributes to the death-rate but plays a econdary rôle to poverty itself Climate is at most f minor importance Analysis provided no clear vidence that overcrowding increased mortality from eumatic heart disease, though it has been clearly own to increase mortality from pulmonary tuber- ulosis A possible interpretation of this remarkable iscrepancy is that acute rheumatism does not spread y droplet infection, poverty would then play its art only after infection has been acquired Statis- ical analysis may thus have provided a clue to the way in which the disease is transmitted that should be looked into

Since they are the outcome of poverty, acute rheumatism and rheumatic heart disease must be regarded as preventable Whether rheumatism is caused by a streptococcus or a virus, whether heredity plays a part or not, the mortality and invalidism from the disease will fall as soon as the load of poverty is lightened This is one aspect of a many-sided problem which confronts the new advisory committee, appointed on June 30, whose joint secretaries are Mr **NORMAN CAPENER** (British Orthopædic Association) and Sir **FRANK FOX** (Empire Rheumatism Council) Perhaps, too, the social and preventive medicine committee of the Royal College of Physicians, also formed recently, will consider this question

INCOMPATIBILITIES OF SULPHONAMIDES

IN the early days of sulphonamide therapy severe cyanosis was the most alarming of the toxic effects It was soon recognised, however, that the outlook in these cases was rarely as black as it seemed when taken at face value, and indeed most practitioners disregarded cyanosis in determining the effective dose of the drug **COLEBROOK** and **KENNY**[1] showed that the cyanosis was due to methæmoglobin, or more rarely sulphæmoglobin, in the blood These changes in the blood pigments are representative of a biological mechanism previously described by **SNAPPER**[2] and **VAN DEN BERGH**[3] In the presence of oxygen sulphæmoglobin can be formed in the blood-stream from sulphide absorbed from the bowel, and sulphanilamide is only one of many drugs which facilitate this reaction by acting as catalysts The danger of sulphonamide cyanosis arises from the immobilisation of the body's oxygen carrier Methæmoglobin in the blood is comparatively benign, for it can revert to hæmoglobin spontaneously in the course of a few days and much more rapidly after the administration of methylene-blue - Sulphæmoglobin, on the other hand, is more stable and remains unchanged in the erythrocytes until these are destroyed, which may be a matter of 4 months or so Furthermore, the cyanosis due to sulphæmoglobin is unaffected by methylene-blue Earlier workers were often puzzled by the occasional occurrence of sulphonamide cyanosis without spectroscopically demonstrable changes in the blood That this discrepancy originated in faulty technique seems probable from the investigations of **CAMPBELL** and **MORGAN**,[4] who emphasised the necessity for laking the blood with only a small volume of water and making the spectroscopic examination soon after the withdrawal The present infrequency of gross cyanosis due to sulphonamide therapy as compared with 5 or 6 years ago may, however, be partly explained by chemical differences between 'Prontosil rubrum' and the sulphonamides now in common use

The absorption of sulphuretted hydrogen is said to be favoured by the use of saline purgatives which enhance bacterial activity by keeping the fæces in the fluid state, but this hypothesis does not bear close scrutiny In man, at any rate, only the contents of the colon are likely to undergo any considerable alteration in consistence, for above the ileocæcal valve

wheat berry. The source of the flours used for baking the bread was unknown in many of the samples analysed, for in large bakers' shops this information is not always readily obtainable.

These results, although obtained on bread and by a different method, agree in the main with the survey of flours made by the Research Association of British Flour Millers, who found that the crude-fibre content of 47 out of 303 samples exceeded 0.9%.[6] Thus shortly before the national loaf became compulsory a small but far from negligible proportion of millers were supplying a product which did not achieve the Medical Research Council's aim of supplying the maximum nutritive value and palatability with the minimum amount of coarse material liable to cause digestive troubles.

Since March, when these samples were collected, there has been time for the millers to get more used to producing the national flour, and its quality has possibly improved. Since a straight-run flour of 85% extraction has a lower crude-fibre content than the reconstituted flour,[1] it might be possible, if millers would produce the former type, to reduce the upper limit in the specification of crude-fibre content and thereby ensure for us a national flour of still higher nutritive value and acceptability. In any case, a check on the quality of the national loaf, such as the fragmentary one here described, should be in constant operation, though this will be inapplicable while it is permitted to mix up to 25% white flour with the national flour.

We wish to thank the Biochemical Laboratory and the Field Laboratories, Cambridge, for facilities for carrying out this work.

Reviews of Books

A Practical Method of Self-analysis

E. PICKWORTH FARROW, M.A., D.Sc. London: George Allen and Unwin. Pp. 153. 6*s*.

IT is sometimes said that Freud, who created psycho-analysis, was never psycho-analysed. This is, of course, an error; he analysed himself, and since then others like Roheim have done likewise. An English exponent of the method, Dr. Farrow, now explains how beneficial he found it, after two abortive attempts to submit to the more conventional procedure. Professor Freud, in a foreword, describes him as "a man of strong and independent intelligence, who, probably on account of a certain wilfulness of character, could not get on well with the two analysts with whom he experimented." The matter could not be put more simply, and the qualities referred to by Freud are manifest in the book. It is readable, but on many points out of touch with modern psycho-analytic teaching. When the author says, for example, that he prefers to describe "oral erotism" simply as "hunger" he is by implication attacking the edifice at its base; this comes about through his very personal approach and reliance on his own experience, which makes him at once biased and independent. His experience is intensive; he tells us that the book is the outcome of 2800 hours, spread over 18 years, and of more than twelve million words of free association, which he was accustomed to record systematically. The book is fresher and more stimulating than orthodox psycho-analytic manuals.

Roentgen Treatment of Infections

JAMES F. KELLY, M.D., F.A.C.R., professor of radiology, Creighton University; with the collaboration of D. ARNOLD DOWELL, M.D., assistant professor of radiology in the university. Chicago: Year Book Publishers. London: H. K. Lewis. Pp. 432. 33*s*.

THIS book fills a gap in medical literature. Its authors recognise the importance of X-ray treatment of the infections and have put together for the first time in book form the fruits of their own experience and that of many others. The first part of the book deals with physical and biological considerations and here their guidance is less sure. Their reference to protection, for instance, runs: "All sources of secondary radiation should be ascertained and adequate means of protection provided so far as it is possible to do so"; and under the heading "Training not always necessary for success," they state that infections "may be treated by any physician familiar with the operation of X-ray apparatus, the definition of an r unit, and the disease he is treating"—an odd statement in itself, and a dangerous one in its implications (the definition of the roentgen given in the text is not that which has now been accepted internationally). The second part of the book deals with the treatment of peritonitis, parotitis, pneumonia and other infections, the main section being an informative account of the treatment of gas gangrene of which the authors were the pioneers. They make a good case for the further investigation of this type of treatment, though many of their assertions are controversial. They rightly stress the value of X-ray treatment in postoperative parotitis and similar infections in which this method of treatment deserves further trial. Probably a portable X-ray therapy plant for the treatment of infections will one day form a recognised part of the equipment of all large general hospitals.

The Injured Back and its Treatment

Editor: JOHN D. ELLIS, M.D. London: Baillière, Tindall and Cox. Pp. 377. 30*s*.

THIS collection of nine papers by eminent American orthopædists deals with the common minor injuries as well as the more serious fractures and dislocations, with and without cord involvement. The views expressed are orthodox and set out clearly. A chapter on backache as a symptom of visceral disease might have been more at home in a less practical manual but is welcome all the same. Proper stress is laid on a systematic examination of the back; after reading this chapter most doctors will feel that their previous efforts have been somewhat sketchy, and that there is much more to be learned from a complete examination than they had realised. The rôle of the articular facets in causing back pain is discussed—a syndrome which has not yet received much notice in this country but one described as being fairly common. The editor has minimised overlap and maintained continuity; there are no significant omissions.

Synopsis of Blood Diseases

A. PINEY, M.D. Birm., M.R.C.P., physician to St. Mary Hospital for Women and Children, Plaistow. London: Wm. Heinemann (Medical Books). Pp. 120. 10*s*. 6*d*.

DR. PINEY presents an up-to-date summary of our knowledge of blood diseases without going into detail about the changes in the blood-picture. It will be especially useful to the postgraduate student with an adequate background who wants to revise the subject quickly, but it is probably too sketchy to help the general practitioner without such a background. The main difficulty in blood diseases is differential diagnosis and for this a more detailed description of the results of hæmatological examination than Dr. Piney gives is needed. The treatments advocated are on sound and balanced lines and reflect modern practice, though the use of fortified liver extract occurs in several unexpected places. The four colour plates illustrate blood and bone-marrow cells in a rather unconventional way that is hardly convincing and are unlikely to help the average physician for whom the book is intended; the same must be said of the extensive tables of the characteristics of the various types of cells. Nevertheless this book will have its place as a quick "brush-up your blood diseases."

ms and the chance to talk with friends have as uch weight with children as with their seniors deed many of those who preferred school meals ntioned the conversation of friends as the chief raction Other objections were mainly trifling , e food faddist spoke feelingly of mother " If she ows her child can't possibly eat a certain kind of d without feeling ill, she can excuse her child and her child feels quite happy There are many ings I do not like such as fat on meat, tapioca, stews d many others " Several seemed nervous out their table manners, but in one case at least stom set these doubts at rest " The first few nes I thought I would much rather have my ner at home for no apparent reason now that I k back except that I was rather nervous of eating front of strangers " Some preferred the company their family to that of their friends, and some liked the routine of school meals , to one, indeed, seemed an advantage that home dinner was eaten en it was ready and not at a fixed time One emphasised that at home he had enough time to wash properly before dinner, and that he could use his own towel

On the positive side were liking for school fare, and relief for some children from a long and tiring walk or from the alternative of a packet lunch Many of the older children realised that school meals spared their mothers, and that the food was chosen with thought for their own health and development Schools which grew their own vegetables took pride in the quality of the results, but school gardens were only occasionally mentioned, which suggests that this aspect of school feeding might be developed further As Le Gros Clark points out, these children are still getting accustomed to the idea of school meals If the early stages are well managed they will take the system for granted when their own children are going to school This intelligent survey gives many clear leads to the ways in which the present practice can be established as a custom , and once it achieves that status in England it becomes sacrosanct

ABIOTROPHIES OF RETINA AND CHOROID

THE cause of retinitis pigmentosa is not settled It s thought by some to be due to a failure of the od supply to the rods and cones—perhaps owing to oroidal sclerosis In support of this view were the lowing facts first, the disease starts at the equator the eye, where the blood-supply to the outer layers of e retina is at its poorest, being the junction of the eas supplied by the long and short ciliary arteries condly, Wagemann in 1890 found that experimental tion of the ciliary arteries in rabbits produced pigmenry changes in the retina, though confirmation of this rk has not been forthcoming On the other hand, it s been pointed out that atrophy of the choroid owing prolonged pressure in glaucoma does not produce gmentary changes in the retina Latterly there is ore support for the view that the condition is an notrophic change in the neuro epithelium The term notrophy was introduced by Gowers in 1902 to mean want of durability of the tissues It was not essential at this change should be hereditary, but in fact it was ten found to be so Gowers drew attention to Leber's tic atrophy as an example of this condition, and later llins and Leber included retinitis pigmentosa also he hereditary tendency was extensively worked out by ettleship in 1907, who traced the disease in 976 families one instance following it back through the generations a soldier who fell on the field of Waterloo Now rsby[1] has published records of the disease, and also of oroidal sclerosis and macular dystrophy, in which the reditary and familial tendencies seem beyond doubt hese two latter conditions have not yet had their digrees followed up to the same extent as has retinitis gmentosa , if the same rules apply, then it would pear that they can occur as dominant, recessive or x-linked traits

BLOOD REGENERATION IN DONORS

DURING the last three years, blood donors the world ver have been bled on an unprecedented scale, and it is markable that there have been so few reports on the fect of the blood loss The experience of most of those ho have to do with the welfare of donors seems to have een that the removal of an amount of blood not exceeding 20 c cm at six monthly intervals from adults in ordinary ealth is not in any way detrimental to their well being Opinions differ as to the advisability of bleeding at three-monthly intervals or less under war conditions Fowler and Barer[1] of Iowa city have studied blood regeneration in 200 subjects, mostly young men working in hospitals The average drop in hæmoglobin after the withdrawal of 500–600 c cm was 2 3 g per 100 c cm or 18% The average time taken by 105 subjects to make good their blood loss was 49 6 days, the longest being 98 and the shortest 18 days At the end of eight weeks only 74% had made good their loss There was little appreciable difference in a smaller series where the same amount of blood was removed in two fractions on consecutive days In general the slower rates of recovery were in those who showed the greatest fall in hæmoglobin , the initial hæmoglobin level did not appear to be a significant factor in the rapidity of regeneration Unonius and Schroder,[2] however, found that those with a high hæmoglobin returned to normal more quickly than those with moderate or low hæmoglobin levels Fowler and Barer were only able to observe seven subjects who gave 300 c cm , their recovery period varied from 12 to 65 days with an average of 33 days Only a few women were studied, but the findings suggest that their hæmoglobin regeneration is slightly slower than men's Studies to show if subsequent donations are associated with quicker or slower regeneration are inconclusive , a much larger series would be necessary to establish this point The most striking feature of the Iowa study is the effect of giving daily 1 g of ferri et ammon cit during the recovery period This experiment was made on 89 subjects whose regeneration after a previous donation had already been studied The average recovery time was reduced by 27%, and the daily hæmoglobin gain increased by 49% With subsequent donations iron appeared to have progressively less effect on regeneration No way of predicting the speed of hæmoglobin regeneration beforehand was found Snapper and others[3] found that Chinese donors were prone, presumably on account of their poor diet, to develop a microcytic anæmia, occasionally associated with achlorhydria, glossitis and splenomegaly , they responded rapidly to the administration of iron The reserves of iron carried in the bone-marrow, though adequate for most natural emergencies, are reduced in hæmorrhagic anæmia, and there is satisfactory evidence, according to Schultze,[4] that reaccumulation takes place after iron the fæces are fluid. Thus, only a small part of the alimentary canal is affected. Again, if the amount of water in the bowel increases owing to the action of the saline purgative in preventing absorption, sulphuretted hydrogen, which is fairly soluble in water, will tend to remain in solution in the bowel rather than pass through the intestinal mucosa. Another point which is often overlooked is the importance of the speed of action of the saline purgatives when properly administered. If the bowel is "emptied" by a process equivalent to lavage, and the procedure is completed within an hour, it is reasonable to suppose that there will be a greatly reduced opportunity for the absorption of sulphides or anything else until the cataract has abated. It may be objected that all this is speculative, but is it more speculative than the reasons which were once supposed to justify the prohibition of sulphur-containing foods? Scepticism over the importance of such foodstuffs in the pathogenesis of sulphonamide cyanosis is borne out by Niblock, who gave a diet containing eggs, onions and other foods having a high proportion of combined sulphur to 100 patients receiving sulphonamides. Spectroscopic examination failed to reveal methæmoglobin or sulphæmoglobin in the blood. Again, Smith[6] has shown that sulphapyridine can be given without fear of toxic effects to patients who have received intravenous injections of 'Pentothal sodium,' despite the fact that this compound contains 12% of sulphur. Observations of this kind[7] are to be set against laboratory experiments in which diets and doses bear little relationship to the problem confronting the practitioner. There seems no doubt[4] that the administration of sulphur in the uncombined state does produce methæmoglobin (and occasionally sulphæmoglobin) in a certain proportion of patients receiving sulphonamides, but now that confection of sulphur is among the forbidden fruits of the pharmacopœia few practitioners are likely to use this drug as a laxative.

Recent work suggests that the sulphonamides should be avoided when quinine is being given. Niblock[5] observed that in 6 patients treated with quinine and sulphonamides simultaneously vomiting occurred in every case and recovery was slower than was expected. Pharmacological confirmation of this clinical observation comes from Harned and Cole,[8] who have shown that in rats receiving sulphapyridine and quinine the absorption of the sulphonamide is increased on the average by 44%, and there is a corresponding rise in the amount of acetyl-sulphapyridine in the urine. The largest dose of quinine given almost doubled the output of acetyl-sulphapyridine. They found no corresponding rise in the volume of urine secreted during these experiments, and this curious effect of quinine must therefore increase the risk of deposition of crystals in the kidney tubules. It would be interesting to know whether sulphonamide quinine therapy in the human subject produces impairment of renal function, for Niblock's observations taken with those of Harned and Cole raise the possibility that this combination of drugs may produce uræmic symptoms. When mepacrine hydrochloride ('Atebrin') was substituted for quinine in the experiments on rats the alterations in absorption excretion of sulphapyridine were not observed this country the occasions when sulphonamides and quinine are used together for combined malarial and bacterial infections must be rare. But in tropical subtropical countries this incompatibility will have to be borne in mind.

THE FUTURE OF THE SCHOOL CANTEEN

The numbers of children taking dinners in school, according to J. Alison Glover,[1] should reach a million by September of this year; but hopes that school meals on a large or even universal scale have come to stay, must depend ultimately on what the children think of them. In an inquiry[2] undertaken by F. Le Gros Clark for the education committee of a home county, the children's views have been directly canvassed. Lest there should be any element of posing for the camera in their replies, the subject was set as an ordinary class essay, and the children were told nothing about the inquiry. The Hertfordshire schools which took part represented every type of urban and rural district, and the first 600 essays were drawn without selection from the first 18 schools, and analysed.

Answers were most spontaneous and frank from children between 9 and 11; the 13 and 14 year-olds were more consciously concerned with the technique of composition; but most of them expressed an honest preference, one way or the other, for school or home meals. About 31% of the boys and 35% of the girls favour school meals; 45% of boys and 41% of girls favour home meals; the rest were doubtful, indifferent, or did not state their preference. At first sight it appears disappointing that a larger number prefer home meals, but when the reasons for this preference are considered it becomes clear that many objections could be overcome by better management of school feeding. That many of the bigger boys complain of leaving the table hungry is a complaint which calls for obvious and immediate remedy. The adolescent appetite always has to be seen to be believed, and the lad who wrote "a boy of fifteen eats a man's dinner" was probably underestimating, if not his own needs, at least his own capacity. Those who complained that the helpings were all the same size, and that the little ones got as much as the big ones admitted reasonably enough that as everyone paid 4*d* this lack of discrimination was fair; but they were still hungry. At home, no doubt, they would make out on hunks of bread, but the schools, in an effort to provide a properly balanced meal within an economic framework, are presumably hard put to it to give them enough. King Solomon, when he failed to satisfy the hunger of the sea-monster, fell on his face with shame and gave up trying. The schools will have to exceed the wisdom of Solomon by finding way to fill their voracious young diners. Many children objected to crowding and noise; and some points seemed to be lack of drinking water on the tables in some schools, and rules against talking at meals in others. These all clearly spring administrative difficulties which the staff have not yet had the accommodation, equipment or imagination to overcome. Clean and comfortable di the causation of dyspepsia It is permissible to infer at the bolting of meals, or the cramped position of the otor driver for instance, must be factors at work in any of the non-organic indigestions, and that the currence or not of such indigestion will depend at least part on the conditions of tone existing at the time, us in turn depends mainly on conditions of general ealth and in particular on physical fatigue and mental ate It is but a short step from such functional ariations to the secondary changes of gastritis Hence ay arise the many “nervous” dyspepsias in which astritis is also present—but in which no clear physical ause of the gastritis can be found—and in which it is imarily general and nervous factors, mode of life and egime, that require investigation and attention rather han the purely local condition of the gastric mucosa

WAY IN FOR THE POLIOMYELITIS VIRUS

THOUGH Landsteiner and Popper[1] showed as long ago s 1908 that the agent causing acute anterior poliomyelitis was present in the brain and cord of fatal cases and nfective for monkeys, the common portal of entry of he virus in man has not yet been agreed on That the irus was present in the fæces of human cases was shown y Kling[2] in Sweden in 1912 and confirmed by Sawyer[3] n the United States in 1915 For some reason this gnificant fact was lost sight of and interest became ntred on the nasal and nasopharyngeal areas Flexner nd Lewis[4] first propounded the theory in 1910 that the irus reached the CNS from the nasopharyngeal mucosa y passing along the filaments of the olfactory nerves o the olfactory lobes of the brain After this the virus as isolated by numerous workers from the nasopharynx human cases both acute and convalescent and from o called healthy carriers This seemed to be sufficient vidence for most of those interested in spite of the fact hat as a rule the epidemics did not occur at the season hen other diseases spread by droplet infection were revalent In 1938 Sabin and Olitsky[5] observed that, fter nasal instillation of the “MV” strain in rhesus onkeys, the virus was demonstrable in the nasal ucosa and secretions for the first 72 hours, but not at the me of paralysis Sabin[6] also failed to isolate it from he same region after inoculation by the tonsillopharyngeal route Recently Sabin and Ward[7] have failed to nd the virus in the collateral sympathetic ganglia, drenals and salivary glands of fatal human cases ow[8] they have found that after intrasciatic inoculation f the MV strain in 8 rhesus monkeys paralysis developed n 3–5 days and virus was present in the brain and cord ut could at no time be demonstrated in the nasal ecretions Even in the terminal phase the virus had ot spread sufficiently in the CNS to involve the olfactory ulbs and adjacent nasal mucosa and was not present n the collateral sympathetic ganglia, adrenals or alivary glands Their last two reports indicate that oliomyelitis virus after multiplication in the central ervous system probably does not spread outward again o affect the peripheral collections of nerve-cells in various issues They[9] have also failed to find any virus in the asal secretions, saliva and oral secretions expectorated n 20 paralytic cases The tonsillopharyngeal route has tely been discussed at length by Aycock,[10] who concludes that removal of the tonsils definitely increases he chance of infection with the virus of poliomyelitis nd so should be carried out at times of the year when he disease is not prevalent As early as 1898[11] it was uggested that the gastro-intestinal tract was probably he portal of entry of the agent causing the disease n 1938[12] the presence of the virus in the stools of cases f poliomyelitis was rediscovered and the virus has now een isolated from the fæces of many people suffering rom the disease and their intimate contacts Thus angmuir[13] has found that of 33 intimate contacts of paralytic cases four-fifths of those who had symptoms of illness and nearly as many of those who had no symptoms harboured the virus in their stools The virus has also been isolated from sewage on six different occasions[14] in different localities in the USA and once in Sweden[15] Last of all the virus has been found in flies caught in several different localities[16] either on the premises of cases of the disease or at the mouths of sewers draining an area in which cases of poliomyelitis were present All these observations, together with the frequent findings of the virus in the human pharynx and intestine at autopsy,[7] suggest that these are the usual portals of entry in man

NOT FOR US

AFTER what we have been told about the shortage of phenol and its derivatives no one over here is likely to begin trials of a remedy for “athlete’s foot” (tinea interdigitalis), advocated in America, which consists of equal parts of phenol and camphor The phenol is melted and the camphor rubbed into it until the whole mass is liquified A similar preparation of phenol 1 camphor 3 appears in the BPC as phenol or carbolic camphor The fifty-fifty mixture, according to Francis,[1] is non-irritant to the skin and non corroding to clothing It is painted on the affected part several times a day, it must not be applied to wet skin, because water liberates the phenol The application is said to give immediate relief from itching and has been successful in curing tinea cruris A good story has been made out of this treatment in the *Reader’s Digest* for June It appears that Francis was using the phenol camphor mixture as an insecticide in 1907 when he observed that it was non-irritant to the skin and appeared to cure a patch of ringworm on his arm to which he applied it This article has been followed by a popular demand for the mixture in America sufficient to produce an editorial warning in a later issue of the same journal[2] that until more inquiry has been made it should be used with caution and under medical supervision The more so, as athlete’s foot as a rule responds readily to benzoic acid 5%, salicylic acid 3% in the form of Whitfield’s ointment Miller[3] describes a case in Canada which illustrates the possible dangers of a phenol-camphor mixture, in this case in the proportion 4 to 1 A young man had large patches of ringworm on his shoulder, scapular region, arm and trunk covering a total area of 60 sq in He had heard of the phenol-camphor remedy and made himself a mixture of 1 oz camphor and 4 oz carbolic acid, which his housekeeper proceeded to apply to the ringworm Before the application was finished he felt faint and dizzy, so the housekeeper diluted the mixture with water and applied it again Almost at once he became dyspnœic and he died a quarter of an hour after the beginning of the application At the autopsy phenol was found in the internal organs, and death appeared to be due to acute pulmonary œdema In this case absorption was no doubt aided by the inflammatory lesion present as well as by the addition of water to the mixture

administration Recent work supports this view, for Whipple and his associates,[5] using radioactive iron, have shown that absorption from the intestine is controlled by the needs of the body, moreover, it has more than once been suggested that iron administration has a stimulating effect on erythropoiesis It seems rational, therefore, to recommend a short but intensive course of iron after a substantial donation of blood The objections are, first, the inconvenience to the donor and the occasional disturbance of intestinal function which may result, and secondly, the adverse effect which the measure might have on the recruitment of donors It is obvious that only those with a satisfactory hæmoglobin level should be bled, and the routine determination of hæmoglobin content before bleeding is too seldom carried out Using a suitable instrument a reliable assistant can be both accurate and speedy, and he or she should form an integral part of all bleeding teams

ASPECTS OF TWINNING[6]

Professor Newman, well known as a biologist and an expert on twins, has brought together a mass of lore about twins—from the realm of myth and legend and from highly scientific sources such as the Maxim Gorky Medico Biological Institute and Japanese salmon nurseries Ambroise Paré reports that "one Margaret, a woman sprung from a noble and ancient family near Cracovia, and wife of Count Nerboslaus, brought forth at one birth thirty five live children, upon the 20th day of January in the year 1296" Even the Dionne quintuplets hardly rival this Twins raise problems in biology, embryology, medicine, psychiatry, and psychology, and the causation of twinning is a mystery Why should there be a twinning rate in Belgium nearly 200 times as great as in Cochin China? (And why, incidentally, should Great Britain be almost the only civilised land unable to publish official statistics of their frequency?) It seems that there is a hereditary factor in the production of binovular twins, but how is it possible for a father who has inherited the twinning tendency to influence the production of binovular twins by his wife, as some authors maintain? How important is heredity in the production of uniovular twins? Some people say not at all yet the famous Jean Picard, himself a uniovular twin, married a uniovular twin, and there is good evidence for believing that three uniovular pairs were born in succession, though in each case only one of the pair survived Twinning has often aroused speculation about telepathy Professor Newman tells a remarkable story of twins whose answers in examinations were so similar, despite separation by the breadth of the room, that it was decided to examine them in separate rooms On the day, Charles was given his questions but would make no start After a time, the principal came in and asked where the examination questions for Joe had been left, Joe had been kept waiting for half an hour or more When finally Joe was given the questions Charles was able to begin They wrote simultaneously, finished together, and came back to the classroom together The principal was quite excited "Boys," he exclaimed, "your Latin papers are identical, the same words, the same syntax, the same grammar, and the same mistakes! But I am sure you didn't cheat It must be because you are twins" Some of the most interesting work with twins has been done by the co-twin control method, mostly in Russia, until about two years ago For instance, five pairs of uniovular twins were taken and one member of each pair instructed in building with building blocks by one method, their brothers by another In the one method of training, the children, between the ages of 3 and 5, were required copy a structure shown in a picture in which the r of every block was given By the other method, brothers had to copy the same picture but there wa indication of which block went where—the c had to find that out for themselves After two m training, all were given a new and complex structure copy, both by the accustomed and u methods, and were also given a free creation test gress had been slower in the twins who had received lesser degree of help in construction during training, in the test they greatly excelled their twin brothers skill and diversity of manipulation and in the complex of the structures they created

GASTRIC MOTILITY AND DYSPEPSIA

Functional disorders of the stomach make up large proportion of the minor dyspepsias (and not a of the *major ones*) whose exact *mechanism* is still far fro clear Variations in gastric secretion, either in quant or composition, can rarely be correlated with symptom and even complete achlorhydria may be unas with any indigestion Gastric emptying time again vary within wide limits without precisely kno or even any symptom of dyspepsia, and is subject t considerable alterations under changing conditio Peristalsis and tone of the stomach can be studied wi fair accuracy by radiography and we have learnt th it is essentially these factors which are responsible f gastric sensations Normally these two processes harmoniously together and it is when disharmony that symptoms appear, though we cannot al elucidate the precise causes and factors provoking su disharmony It may often be an alteration in nervo control, reflexly produced and independent of lo stomach *conditions*, which *is at fault* Wegelius[1] Helsinki, studying such functional problems children, has adopted the method of kymography of stomach, as first introduced by Stumpf in 1936 By means the movements of the stomach are record graphically, and kymographic records are made lastu 60–90 seconds each for at least two consecutive perio so that the complete movements of the stomach can it were be watched objectively for a relatively long tim In this way, as compared with the short exposures us in normal radiography, a clearer insight into both to and peristalsis should be possible, and the two may studied almost independently Not everyone agre about the exact interpretation or value of kymograph but Wegelius's observations are certainly interes Following the work of Weltz he describes three ma types of gastric activity and emptying First, t peristaltic (normal) type, in which emptying of t stomach depends on a satisfactory filling of the p pyloric canal, which in its turn depends on a we balanced tone Such emptying is independent of po tion and internal hydrostatic pressure Secondly, a t in which tone is variable and filling of the prepylo canal is poor here the gastric contents are pass on unevenly and the emptying is to some exte dependent on posture and internal hydrostatic pressu Thirdly, a definitely abnormal type in which is completely asystomatic The stomach then itself like a lifeless tube, according to the hydro pressure inside Thus if it is filled rapidly in t upright position it empties equally rapidly ("Sturze leerung"), small amounts of food may on the co trary be retained over long periods and may only passed on when this residue is made to enter the p pyloric canal by the patient lying down, or by directed towards the pylorus Between these types are many gradations This closer analysis gastric motility suggests again the importance of simple matters as posture and the rapid eating of r industry An ophthalmic surgeon has no more t to be exempt than a skilled electrician nor can laim special consideration on account of risk to the munity We are all now suffering these risks from tion among skilled electricians and engineers and all grades of skilled workers upon whom we rely y time we enter a 'bus or a tube-train or even our house, although half the time we are unconscious

[1] Wegelius, C *Nord Med* 1942, 14, 1020

he majority of health workers, however, are not red in industrial units So far as they work in ips the greater number are based on hospitals A ital, if you like, is the nearest approach to a factory he health industry Of course, workers in hospitals see their link with industry easily when accidents n the bench come in and they return the worker in imum time back into production But catering for treatment of all sickness and injuries in society means ter efficiency for that society and a production drive, n translated to the hospital, becomes an efficiency ve We must keep our health services and our pitals up to the maximum pitch of efficiency as our her contribution to the industrial production drive

eports are now coming in on the success of production mittees in factories Should there not be some allel in a hospital to these production committees in actory ? The organisation of a hospital is more plex than any other unit that I can think of, so that eems more than ever necessary to consult the various, sibly contending, interests on organisational matters of the strongest recommendations in the Athlone mittee's interim report on nursing was that there uld be nurses' committees in every hospital I der in how many hospitals this has been acted upon, if it's necessary to have a medium for the expression nurses' interests it can be no less important to have for the domestics, porters and technicians

f one section of a group understand how their interests n with other sections, there is more likely to be good mwork when heavy demands are made upon the ole group But it is important to get together for er reasons Many nurses are full of ideas on how to anise ward work better, but cannot get heard in the at quarters I'm certain many surgeons could learn rick or two from the hospital plumber, carpenter or gineer, and why don't physicians consult the kitchen ff more ? Then there are still patients who get good as Look up the letter from a patient on the design the bedpan and the capacity of the urine bottle[2] ny of them have ideas about evening clinics and out-tient appointments too We must tap all these ideas our hospitals That is what is being done in industry lay by production committees and there are already ny remarkable stories of their achievements

Industry is striving in other directions For instance, ey are bringing women into men's jobs wherever ssible Are we making it easy for women to train emselves and take the place of men ? Have we rown open every teaching hospital to women students a par with men ? If we haven't then we are lagging hind the best workers in industry In the USSR even peace-time 70% of the doctors were women Industry is examining jobs to see if the highly skilled people employed on highly skilled work Have we rational- d our industry ? How many nurses—and nurses are ry scarce—are doing work which wastes their training d technical skill ? I heard of a sister taken off a sualty department and put in the stores, virtually as lerk, I know of a hospital where all the nappies in the nts department are washed by nurses Do doctors e clerks enough ? The other day a house-physician nt me a long report in duplicate and he hadn't even ed a piece of carbon paper Do we use the dictaphone ough ? Is machinery for domestic work used to e maximum extent ? Domestics are very scarce too d more than ever we must extend the use of machines

* * *

Finally, does the health industry practise what I pe it's going to preach to other industries ? Does it aintain the health of its own workers ? Most hospitals n't even begin to record sickness properly among their aff Nurses usually have individual sickness records t few hospitals can tell you the average days lost annually among first-year probationers compared with third-year or compared with staff nurses or sisters Even individual records of domestic staff are rarely kept We are right behind the Ministry of Supply factories in this Do we correct refraction errors in our staffs ? Do we X ray all nurses and ward maids ? Do we do this that and the other to maintain them at their best health level and make sure of one essential for efficiency ? No health worker need feel that there is not important work for us to do immediately, if we wish to line up with the tremendous production effort in industry

In England Now

A Running Commentary by Peripatetic Correspondents

SURELY it was Mrs Grundy herself with the ghostly eye of good Queen Victoria upon her, who drew up the rules of procedure for women's recruiting boards Each recruit is examined first by a male and then by a female doctor From the neck to the knee the Wren of the future shall, according to the regulations, remain an unprobed mystery for the male doctor He is allowed gently to tap the patella tendon but the joy of stroking the soles of her feet is denied him That only the lady doctor may do, decently shrouded behind the thickest of curtains He may ask whether she has fits or flatulence or whether when she eats marmalade the top of her head steams (this, according to Commander Campbell of the Brains Trust is a well-known manifestation of allergy), but never may he inquire as to the regularity of her periods In spite of all these precautions last week a stout matron in black alpaca and feather boa insisted on chaperoning her daughter through the Board, having heard " what dreadful goings-on " happen there Then suddenly Mrs Grundy unbends and the mere male is asked to give the colour of the recruit's eyes and hair and to describe her complexion, a generous gesture which a niggardly government quickly smothers by allowing one word only for each Only one bare word to describe those eyes as deep as the brown pools of Western Eire one word for the glory of the cunning of peroxide ! For the complexion, were there but room, I would call to my aid the description of a sweet pea given in my favourite seed merchant's catalogue " A bewitching combination of flesh pink richly overlaid on a cream ground Slight shading in hot weather is essential to retain its delightful colour "

Coming from men's boards I notice that the female pulse rarely rises above the hundred mark during examination as the man's invariably does, " and blood lies quiet for all you're near " The modern young lady takes life very calmly But oh, oh the halitosis It is told of Queen Anaitis of old that she kept an asp in such a place as to discourage love-making Surely halitosis is as effective and almost as deadly a protection I might have suggested this to the stout party in black alpaca

* * *

The most obvious and prosaic reason for doing a round on horseback is that it saves petrol and wear-and-tear of precious tyres Another, more personal, reason is that it exercises a middle-aged body and, in the words of the patient, shakes up the liver—though why that long-suffering gland should be the better for being shaken up I leave to the physiologists to answer Horses will go along tracks and lanes where cars cannot, horses don't have to be steered—at least, not to any absorbing extent—and from the saddle one does literally see things from a new angle Being perched up in the air one can even look over our high Devon hedges and take a view at once leisurely and appraising of Farmer Blatchford's bullocks and Farmer Burrington's " yowes " Passing various homesteads at a stately pace one can ruminate upon the numerous dramatic illnesses attended therein—that cottage, for example, where the eldest boy so unexpectedly and tragically died of meningitis after mumps, that other cottage which was the scene of a difficult breech-delivery, that farm where the farmer had pneumonia, in the presulphanilamide days, which caused such alarm and despondency in the household until he successfully weathered it, and the parsonage in which, a dozen years ago, the then incumbent was operated upon for acute intestinal obstruction There are also the birds to be seen, the daws and rooks, the fat wood-

HEALTH WORKER AND PRODUCTION

T O GARLAND M D CAMB, D P H

THINGS are altering, but there's still little conscious relation between the methods and relationships of production and the medical student's curriculum I can only speak accurately of my own experiences We used to fill in the line on the case sheet that started with the word "Occupation," but many a time the patient's answer meant nothing to us, while the inquiry was never pushed as far as a visit to the factory or dock where the accident had occurred While we learned that diseases like lead poisoning occurred in painters, we learned nothing about the measures that could be taken at the site of work to prevent this happening While we had vague ideas that tuberculosis was associated with social conditions, we did not write a sociological background to the TB case illustrating how the hours of work and length of journey were related to the fatigue that had lowered the resistance, nor did we write our reports on cases of anæmia, illustrating how the wages or family budget were related to the state of nutrition

Historically, we were still worse off I can never remember any mention in a lecture of the mass ill health *resulting from the conditions of production in 1820–30* The fact that vast epidemics of cholera swept through the country as a result of the chaotic crowding in unplanned and insanitary towns was news to me four years after I had qualified and was studying for the DPH Till then I believed that cholera had never occurred in England, but was confined to the tropical countries We were never offered an explanation why the highly developed technique of the physicians and surgeons who taught us was so vastly removed from the primitive health conditions that we suddenly met on the district—knowledge and technique on the one hand, filth and malnutrition, overcrowding and chronic ill health on the other The explanation is only to be found in a historical study of the production methods and relationships of our society, but this we were never offered

Today, this black-out on health in the factories, workshops and offices, pits, quarries, and shipbuilding yards must be torn down Everywhere the cry is production and our training and interests, whatever they may have lacked, impress us that the healthy worker produces more than the unhealthy, and this sets each of us thinking, "What is my rôle?"

Health workers must not only cut down casualties in the industrial army, we must maintain the health of its members at the highest possible level The first step is to make available to workers, managers and Government alike the knowledge that we possess for maintaining and building up health We must talk *in language free from* medieval sorcery and modern humbug The widespread neglect of simple health measures in industry is not only a reflection on the organised working-class and the capitalist, it reflects an apathy and lack of social responsibility in health workers

* * *

Casualties in industry from sickness and accidents are high According to the first annual report of the Birmingham Accident Hospital there are now 100,000 accidents a year in that city alone requiring hospital treatment, many of them only as outpatients, but they all entail loss of time Many kinds of industrial illness are increasing too Dermatitis, for example, can be largely prevented by cleanliness, washing facilities, dust control, and protective clothing Why then is it so sharply increasing? Go around and inspect the cleanliness and the washing facilities in factories and you will soon learn one reason Cowsheds have been cleaned up enormously in recent years, let us at least do for our factories what we've done for cowsheds

Accidents or illness figures for the whole country are practically impossible to get hold of The Approved Societies used to make returns to the Ministry of Health, on illnesses of three days and over among their members In 1933, when these figures were last published, the total for the year amounted to 29 million weeks It's almost certainly much higher now and 30–40% of industrial sickness absence is probably from illness of under three days' duration I don't think we should be far out today in putting the yearly loss from sickness in ind workers at about 40 million weeks But these are far from accurate and straightaway we see one of essential needs of proper health planning—the l of proper sickness and accident records You c plan for health without recording ill health Some the large factories in the war industries are recording an absenteeism among the women of 15% This is a on account of all causes, many of which won't be illness, but it is equivalent to an absence of 7–8 working weeks in a year

I think we fall down badly in not keeping the organised working-class sufficiently aware of what are the principal elementary conditions for healthy work We don't constantly emphasise in simple language the scientific requirements of lighting, ventilation, dust control and washing facilities We don't constantly emphasise the dangers of over-fatigue and how it must be counteracted by rest-pauses or prevented by better transport facilities We don't emphasise the paramount importance of good meals during the working shift If we can get the organised workers really conscious about these matters, the battle will be nearly won, for the legal requirements are already largely provided in the 1937 Factory Act But what can a mere 300 odd inspectors do to see that the act is observed in 250,000 premises? A little more certainly than the single medical inspector for all our mines and quarries—our most dangerous industry and one employing over three-quarters of a million men He can have little more time than allows him to dash from one serious accident to another Safety and health regulations will never be observed properly until the *workers themselves understand them and see that they* are kept

The Royal Society of Medicine recently had a discussion on dermatitis in industry where one speaker referred to workers as "unthinking asses" This is an attitude sometimes met with among health workers towards other workers We find them strangely ignorant on elementary facts about physiology, hygiene, dietetics, parasitology and so forth But the mass the workers have left school at fourteen and who helped them learn about these facts since? Has the health profession done much? Mighty little, I suggest When a consultant accuses them of being unthinking he really means ignorant, and I would ask him what has he done to help them to know? That is one of our foremost tasks, to make our technical knowledge available so that the mass of the workers become conscious of the relation between health and production This is a task that is technically simple We haven't got to teach them complicated anatomical relations, or the meaning of our abstruse technical terminology, but we have got to plug these simple requirements for healthy work with proper scientific data that people with an elementary education can easily understand Very often workers find it difficult or impossible to get a simple honest statement about the exact dangers of the substances they are working with It would be a huge mistake to suppose that workers are so unthinking that they don't want to be healthy, or that they don't want to be free from accidents

* * *

The medical and nursing forces available at the actual site of production are today limited Even if we got a fair proportion allotted for work as medical inspectors of factories and in big industries as whole-time medical officers and had established in every fair-sized works whole-time qualified nurse, we should not begin to have enough to cover the whole industrial field We must prepared, therefore, to use to a much greater ex people with short training in hygiene and accident vention as our assistants in this industrial health dri The attitude of some doctors who try to curtail activities of the industrial nurse rather than dev them is deplorable So is the attitude of some sultants, *such as eye surgeons,* who try to restrict use of opticians in factory work[1] In normal times w we can train adequate forces we would all wish firmly maintain the highest standards of qualification for t nical work, but in war-time, with greatly depleted fo health workers must accept reasonable dilution like r industry An ophthalmic surgeon has no more to be exempt than a skilled electrician nor can laim special consideration on account of risk to the nunity We are all now suffering these risks from ion among skilled electricians and engineers and all grades of skilled workers upon whom we rely y time we enter a 'bus or a tube-train or even our house, although half the time we are unconscious

---

[1] See *Brit med J* May 16, 1942, Suppl p 195, and *Dioptric* June 5, p 69

ie majority of health workers however, are not red in industrial units So far as they work in ps the greater number are based on hospitals A ital, if you like is the nearest approach to a factory ie health industry Of course workers in hospitals see their link with industry easily when accidents the bench come in and they return the worker in imum time back into production But catering for treatment of all sickness and injuries in society means ter efficiency for that society and a production drive, n translated to the hospital, becomes an efficiency e We must keep our health services and our itals up to the maximum pitch of efficiency as our her contribution to the industrial production drive

eports are now coming in on the success of production mittees in factories Should there not be some illel in a hospital to these production committees in actory? The organisation of a hospital is more plex than any other unit that I can think of, so that ems more than ever necessary to consult the various, ably contending, interests on organisational matters

of the strongest recommendations in the Athlone mittee's interim report on nursing was that there ıld be nurses' committees in every hospital I ider in how many hospitals this has been acted upon, if it's necessary to have a medium for the expression iurses' interests it can be no less important to have for the domestics porters and technicians

f one section of a group understand how their interests n with other sections there is more likely to be good mwork when heavy demands are made upon the ole group But it is important to get together for er reasons Many nurses are full of ideas on how to anise ward work better, but cannot get heard in the it quarters I'm certain many surgeons could learn rick or two from the hospital plumber, carpenter or ineer, and why don't physicians consult the kitchen ff more? Then there are still patients who get good as Look up the letter from a patient on the design the bedpan and the capacity of the urine bottle[2] ny of them have ideas about evening clinics and out-ient appointments too We must tap all these ideas our hospitals That is what is being done in industry lay by production committees and there are already ny remarkable stories of their achievements

Industry is striving in other directions For instance, ey are bringing women into men's jobs wherever ssible Are we making it easy for women to train emselves and take the place of men? Have we own open every teaching hospital to women students a par with men? If we haven't then we are lagging hind the best workers in industry In the USSR even peace-time 70% of the doctors were women Industry is examining jobs to see if the highly skilled people e employed on highly skilled work Have we rational-d our industry? How many nurses—and nurses are ry scarce—are doing work which wastes their training d technical skill? I heard of a sister taken off a sualty department and put in the stores virtually as lerk, I know of a hospital where all the nappies in the ints department are washed by nurses Do doctors e clerks enough? The other day a house-physician it me a long report in duplicate and he hadn't even ed a piece of carbon paper Do we use the dictaphone ough? Is machinery for domestic work used to e maximum extent? Domestics are very scarce too d more than ever we must extend the use of machines

* * *

Finally, does the health industry practise what I pe it's going to preach to other industries? Does it aintain the health of its own workers? Most hospitals n't even begin to record sickness properly among their aff Nurses usually have individual sickness records it few hospitals can tell you the average days lost annually among first-year probationers compared with third-year or compared with staff nurses or sisters Even individual records of domestic staff are rarely kept We are right behind the Ministry of Supply factories in this Do we correct refraction errors in our staffs? Do we X ray all nurses and ward maids? Do we do this that and the other to maintain them at their best health level and make sure of one essential for efficiency? No health worker need feel that there is not important work for us to do immediately, if we wish to line up with the tremendous production effort in industry

The most obvious and prosaic reason for doing a round on horseback is that it saves petrol and wear-and-tear of precious tyres Another, more personal, reason is that it exercises a middle-aged body and in the words of the patient, shakes up the liver—though why that long-suffering gland should be the better for being shaken up I leave to the physiologists to answer Horses will go along tracks and lanes where cars cannot, horses don't have to be steered—at least, not to any absorbing extent—and from the saddle one does literally see things from a new angle Being perched up in the air one can even look over our high Devon hedges and take a view at once leisurely and appraising of Farmer Blatchford's bullocks and Farmer Burrington's "yowes" Passing various homesteads at a stately pace one can ruminate upon the numerous dramatic illnesses attended therein—that cottage, for example where the eldest boy so unexpectedly and tragically died of meningitis after mumps, that other cottage which was the scene of a difficult breech-delivery, that farm where the farmer had pneumonia, in the presulphanilamide days, which caused such alarm and despondency in the household until he successfully weathered it, and the parsonage in which, a dozen years ago, the then incumbent was operated upon for acute intestinal obstruction There are also the birds to be seen, the daws and rooks, the fat wood-quoted in the Scottish debate on July 8 when, as is customary, the estimates for health and education were dealt with together Mr T JOHNSTON, secretary of state for Scotland, said that if we could emerge from this war with our liberties and our freedoms intact, our health front unbroken, and high standards of nutrition and citizenship in our schools, little else mattered One fair measuring-rod of general health was the condition of the children at school and despite an increase in most respiratory diseases and in cerebrospinal fever, and the disturbingly high infantile mortality, school reports for 1941 so far received were encouraging And they intended to see that the system of nutritious school dinners, with all its potentialities for a still greater improvement in the children's physique, was pushed to the uttermost Glasgow reported that measurements of some 14,000 school-children taken in September, 1940, and April, 1941, showed an improvement on 1939 measurements especially as regards school entrants, and the report for the year ended July, 1941, told of consistent improvement in the physical condition of children of 5–13 The 1941 figures showed an increase over the figures for 1935–39 of 0 47 in, 1 07 lb for five-year-old boys and 0 77 in and 2 96 lb for thirteen-year-old boys, of 0 38 in and 0 95 lb for five-year-old girls, and 0 52 in and over 1½ lb for thirteen-year-old girls The increase of about 1 lb in weight for the five-year-old boys and girls was unexpectedly high and suggested an immediate response to the supply of milk to children under school-age The allowance of meat to school feeding-centres was worth 2*d* per child per day, as against 1*d* in catering establishments for the general community In Scotland 80,000 school-children were now supplied with a substantial meal each day, 20,000 school-children got soups during the winter, and milk was supplied to over 500,000 school-children Industrial canteens and British restaurants were playing their part in feeding the Scottish people

---

[2] Brit med J June 6, 1942 p 710

Mr Johnston is however much concerned at the infantile mortality rate which has risen from 68 per 1000 births in 1939 to 78 in 1940 and 83 in 1941 He had asked the Department of Health's scientific advisory committee under the chairmanship of Sir John Orr to report as quickly as possible on the causes of this rise and to suggest remedies, and a sub-committee of twelve experts on child health had been coopted Meanwhile the figures so far for this year showed improvement

Against the main block of *infectious diseases*, said Mr Johnston, they were in the main holding their own, particularly over the last pre-war year, 1938 Scarlet fever was down by half, diphtheria was up, although it was down from 1940, enteric fever was up, whooping-cough was also up, and the figure for *measles* was down Of late the average annual notifications of diphtheria were about 10,000 In 1940 they rose to 15,711 In 1941 they had fallen to 13,586, so far in 1942 they were back again to just about 10,000 There were now 73% of school-children immunised in Scotland, and 58% of pre-school children They had traced the conditions as regards immunisation of 428 out of 466 fatal cases of diphtheria among children last year Among the immunised children there was only one death out of about 1000 cases who contracted the disease Among the non-immunised children there were 427 deaths out of about 7000 cases Mr Johnston briefly described the Glasgow smallpox epidemic and said that the population had responded smartly to the medical officer's appeal to be vaccinated

Several MOHs averred that since the war there had been a considerable increase in *venereal disease* in Scotland and the Department of Health were considering whether any further measures of control were possible By all accounts there was a vast and disturbing increase in *scabies*, and the 1941 order giving power to inspect premises and examine and treat persons in a verminous state was now being operated in many parts of Scotland Cerebrospinal fever was still five times the pre-war figure, but in t[illegible] of 1942 it had declined *Tuberculosis* [illegible] an upward tendency, the notifications f[illegible] 800 cases more than in 19[illegible] the health of Scotland [illegible] is an acute domestic fuel [illegible] lies were as necessary [illegible] ance, and he urged local authorities and private citizens to lay in re-of cut timber

In pre-war years Scotland was short of some hospital beds Now as a result of the war the Gover-ment owned in Scotland 9 first-class acute hospitals w 8000 beds and 66 convalescent hospitals with 3800 b which so long as they were not needed for war casualt could be used to reduce the waiting-lists of the v hospitals Already 6000 patients had been dealt w

In the Clyde basin an important experiment preventive medicine was being tried out Any panel patient of 15–25 might be referred to the reg medical service by his panel doctor for specialist nostic assistance, and where necessary treatment convalescence in the State hospitals free of charge T scheme began in January this year and by July so 610 cases difficult to diagnose, and caught perhap in time, had been dealt with The hospital doct recommended the Ministry of Labour to transfer patients to more suitable employment so as to facil a cure He hoped to see this system greatly extend both in age-groups and areas

Housing conditions in Scotland were so terrible th not even in the interests of the war effort could th afford to stop building houses that had been alre begun and accordingly since the outbreak of war nea 28,000 houses had been completed

Mr Johnston found the increase in juvenile del quency alarming There was an increase of 3500 (22%) over 1938 It was disturbing that 6752 of prosecutions were for theft, and 2883 for housebre More than half the children were under 14 No d we must increase our approved schools but he regar these institutions as a confession of the failure of soc to provide playing fields We should use our sch less for training memory and more for training citize

DEBATE ON MINISTER'S STATEMENT

Many members in the debate spoke movingly of t suffering caused by Scotland's housing problem Lie Colonel WALTER ELLIOT said we must face the fact th the curve of tuberculosis notifications is moving ag us It was a disease regarded with great fear but thought it not unreasonable to ask the younger gener of women to accept tuberculosis nursing as a form war service Mr M K MACMILLAN paid a tribute the Minister's effort to establish an irreducible of children's rights and said his nutritional policy inevitably linked with reforms in education

Mr WESTWOOD, the under-secretary, who wound the debate, gave details of areas where local authori or doctors, had refused to work under the scheme f maternity benefit There was no scheme in operati for instance, in Argyll, but a meeting had been arra with the doctors All the doctors in Dumbarton except those in Helensburgh, had agreed to work t scheme In Orkney county the scheme was not operating, but meetings were being held between offi of the Department of Health and the doctors Selkirk county the doctors had refused, but the m was being taken up with the BMA Meetings with doctors had been arranged though the scheme wa yet operating in the following areas Ayr bur Dundee burgh and Kirkcaldy burgh In Clydet burgh a scheme was in operation although only doctors had agreed to give their services In the main doctors had tried to come into the scheme L county had a scheme which was not yet submitted Dumfries burgh the scheme was not in operat and from the City of Edinburgh they had had a sch submitted in draft Glasgow had been allowed to p pone bringing the scheme into operation until Decem It was owing to the action of some doctors t schemes are not everywhere in operation Mr Ma interjected that doctors in Scotland were not a set body of men, and if they objected to doing a they had some good reason for it Surely the Min would try to meet the difficulty Mr WESTWOOD reje that the arrangement had been made with the but that some of the local branches refused to ac the terms arranged by the parent body Cr Mr Westwood said that nearly 5000 members of Civil Nursing Reserve were employed in hospitals 200 nurses were needed for the [illegible] service

QUESTION TIME

Sanatorium Waiting Lists

rd Snell informed Lord Davies on July 8 that on March iere were 1507 people in England and 400 in Wales who been on local authority waiting-lists for institutional ment for tuberculosis for more than ten days In Scot- 652 people had been awaiting admission for more than days

Shortage of Midwives

r D L Lipson asked the Minister of Health if, in view of great shortage, especially in reception areas, of nurses ied to deal with maternity cases, he would enrol a mobile id of nurses who would be willing to go, when required to s where they were most needed —Mr E Brown replied need for relating provision for maternity cases to move its of population has been recognised and the supply of wives in reception areas has been increased by transfer by recall to practice My information is that the ciency is rather in the total number of midwives available n in maldistribution, and I do not think, therefore, that a ile squad would assist

Infected Milk

Ir David Adams asked the Minister whether he was aware t persons suffering loss and damage through illness trace e to infected milk unfit for human consumption had a right iction against vendors of such milk, and whether, as the ncial circumstances of poorer citizens prevented their ing such action, the local authorities in such cases make gratia payments —Mr Brown replied I am aware that ertain circumstances there may be a right of action, but m not aware that local authorities make such payments Adams Does the Minister not consider that the local horities ought to have power to recoup sufferers in their as? Mr Brown It is not quite as simple as that In absence of negligence by the vendor there is not a right of ion in every case (See judgment of the Court of Appeal *Square v Model Farm Dairies (Bournemouth) Ltd.*, *nes Law Report*, 55, p 384) Dr E Summerskill es the Minister not agree that unless he presses for an endment of the national milk scheme, which comes into ration in September, and arranges for the purification of milk, the Government will be morally responsible for the semination of tuberculosis?—Mr Brown Everything being done that is practicable in view of war conditions

Prices of Artificial Limbs

Sir W Womersley informed Mr F J Bellenger that his partment had contracts with manufacturers of artificial limbs d carried out costing investigations to control the prices of abs supplied at public expense —Mr Bellenger Are not ost of the artificial limbs used in Ministry of Pensions spitals supplied by private manufacturers under contract, d is the Minister aware of the wide discrepancy in prices of abs supplied to him and those supplied to members of the iblic?—Sir W Womersley I am responsible for supplying nbs to persons disabled by enemy action and as a business an turned politician I see that we get them at a right and fair ice. Facilities are provided by the committee of Roehamp-n Hospital to deal with civilian cases on good terms

Reproduction Rate

Mr Ivor Thomas asked the Minister of Health whether the cently disclosed increase in the net reproduction rate from 75 to 0 80 represented a real increase in fertility or was only ie result of the fuller information obtained under the Popula-on (Statistics) Act —Mr Brown replied The figure of 0 75 as an approximation only, adopted pending the provision fertility data under the Population (Statistics) Act which ve enabled the net reproduction rate to be more correctly sessed at 0 80

Prosecution of a Medical Author

Mr R W Sorensen asked the Home Secretary whether is attention had been drawn to the recent prosecution of the iedical author and the publishers of an alleged obscene book, hether he was aware that the jury returned a verdict of not uilty and the judge dismissed the case, why the proceedings ere instituted, and whether he was satisfied that those who itiated the prosecution were fully competent to discriminate etween obscenity and the serious consideration of biological nd psychological questions —Mr O Peake replied The ttention of the Home Office having been drawn to this book it was referred to the Director of Public Prosecutions, and after full consideration the prosecuting authorities decided that there was prima facie a case for seeking the decision of a court The book was accordingly submitted to the chief magistrate at Bow Street, who granted process at Common Law against the author and publishers The case was heard at the Central Criminal Court If the suggestion is that acquittal by a court necessarily implies that proceedings ought not to have been taken I am unable to agree —Mr Sorensen Is it not desirable to distinguish between pornography and literature of this kind Mr Peake There is no kind of censorship and in a case of this kind it is impossible to predict with absolute accuracy what the findings of a jury will be I think that in this case both the Home Office and the Director of Public Prosecutions have shown a commendable vigilance

Calling-up of Medical Assistants

Sir Leonard Lyle asked the Minister of Labour whether, in view of the serious shortage of doctors now available for the civilian population, he would allow the maximum leniency with regard to the calling up of their essential staffs, such as dispensing and surgical assistants and secretaries —Mr George Tomlinson replied Arrangements have already been made for safeguarding essential female staff employed by doctors Qualified dispensers are not being withdrawn from their employment and applications for the deferment or retention of secretaries and other assistants are considered individually in the light of their qualifications and the possibility of effecting adequate substitution.

Work on the Fields for Mental Patients

Arrangements have been made for suitable mental patients to be accommodated in hostels and to be employed in agriculture under the directions of county war agricultural executive committees Institutions have also been urged by the Board of Control to organise working parties to help farmers with seasonal work. There are few suitable patients available who are not covered by these arrangements or employed in the institutions' farms and gardens in the production of food for consumption in the institutions (Mr Tom Williams replying to Sir Ralph Glyn)

"FIGHTING FOR WHAT?"

Food, shelter and a job are the three primary necessities of life, and this war will not really have been won until a fair share of these are assured to all peoples in all lands That, in brief, is what we are fighting for, and Sir John Orr points out in a 90-page brochure (Macmillan, 2s 6*d*) that unless the united nations can establish an economic system which will ensure that the food necessary for the world community is produced, exchanged and distributed in accordance with need and not profit there will be no firm foundation for an enduring peace Similarly if proper housing furniture, heating, sanitation and all the amenities of civilised living are made available to all those needing them, and not just to the few who can afford them, more than enough jobs will be created after the war for all those now engaged in the armed forces and the war industries Otherwise these will be demobilised into another peace-time army of unemployed

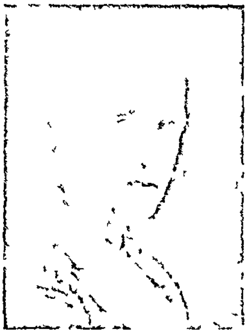
In previous books Orr has directed public attention to the importance of proper nutrition and the prevalence of widespread malnutrition He is not, like some scientists, content to state the facts of his researches and leave it at that He believes that this war has shaken up people's ideas and that we need not go back to the prewar world with its slums, unemployment and poverty People are demanding a policy that will give them freedom from fear and freedom from want, and the book is his attempt to outline the basis of the new world which will secure this Many will read this book with interest and find it the voice of their own aspirations Some may have doubts about the ultimate result of some of his proposals a National Service Corps, for example, would affect workers very differently under socialism and under capitalism The author appears to envisage a marriage of the two regimes He has great faith in the final triumph of what ought to be, but will it be possible to establish the new order simply by wanting a better life for all peoples? We must discover the economic and political causes of our past and present troubles and face them squarely

Obituary

WILLIAM DUNCAN STURROCK

D S O, D M OXFD

Dr W D Sturrock who died in Oxford on June 29, was with the late F G Proudfoot, an original medical officer of the maternity department of the Radcliffe, and its success as a local hospital service owes a great deal to his work in and for it He was the chief obstetrical opinion and practitioner in Oxford and the surrounding district up to four years ago, when ill-health forced him to curtail his practice His hospital work he performed devotedly until a few months before the end



Lafayette

Sturrock was born in 1880, the son of John Sturrock, ICS, and educated at Charterhouse and Magdalen College, Oxford He obtained a first class in the school of natural science (physiology) and qualified in 1905 from King's College Hospital where he later served as house-physician He then joined Dr W T Brooks in practice in Oxford For his service in France and in Macedonia during the last war he was awarded the DSO in 1918, and he was three times mentioned in dispatches On his return to Oxford he succeeded Dr Brooks as medical officer to Radley College, and later was also appointed medical officer to the Dragon School Oxford In both schools his work was a model of diligence and attention to detail, but indeed nothing he did was showy or shoddy

Sturrock had great charm and kindliness, as his patients well knew But he never pushed himself forward and he had an elusive quality which made him difficult to know intimately He married in 1909 Mary, daughter of Ivor Macpherson of New Court, Topsham, and his only son, Jan Sturrock, is now serving in the Sappers

CECIL JAMES MILLIGAN

B A CAMB, M R C S, SURGEON LIEUTENANT R N V R

Cecil Milligan the son of Dr Wyndham Milligan of Brook Street, W 1, lost his life last November when HMS *Dunedin* was sunk He was born in 1909 and educated at Sherborne, where he was in the late G M Carey's house In 1927 he went to Caius College, Cambridge, and after graduating in 1930 he spent four years in business before beginning his medical studies at University College Hospital It was his ambition to join his father in his practice and his friends thought his sincerity and sympathy fitted him for the work he had chosen Having qualified in 1939 he was appointed RMO at Ashford Hospital and when he returned to London at the beginning of 1940 he became temporary physician to Margaret Street Chest Hospital In June of that year he married Enid Margaret Paull, of Banchory, and soon afterwards was gazetted lieutenant surgeon in the RNVR

Strachan, Aberdeen

WALTER ROSS JORDAN

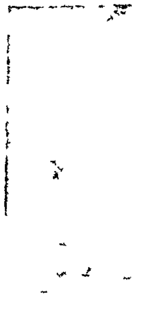
M D LOND

Dr Jordan, who died on June 13, was a member of a brilliant family of physicians and surgeons which, for a period of eighty years, has been intimately connected with the hospital work of Birmingham Although he himself was visiting physician to the Birmingham Municipal Infirmary (now Dudley Road Hospital), his high reputation rested on his work as physician to the Children's Hospital a position which he held for 27 years, and as examiner (like his father before him) for lunacy cases before the Birmingham magistrates was a good clinician, had a love for children and gained their affection, they were attracted by this distinguished-looking and courtly gentleman as his colleagues Jordan had a great sense of h was an excellent after-dinner speaker with a sarcasm that always amused and never repelled hearers He was also a good committee man, and present high standard of the children's hospital much to his clinical and business ability He educated at King Edward's School and Mason C qualifying MB Lond from Queen's College in 1 Throughout his life his old school was one of his interests, he was appointed a governor in the 1917 and remained one until his death and he bailiff of the foundation in 1929 and again in 1940 loved good literature and art and was twice p of the Birmingham Library In politics he was a long Liberal, not always an easy faith to cling to Birmingham He died at the age of 78, a man to whom his younger colleagues looked up with a respect and admiration bordering on veneration

JOHN WENLOCK ASHLEY

B M OXFD, SURGEON LIEUTENANT R N V R

THE Admiralty have posted Dr John Ashley "missing presumed killed on active service,' d June He was born at Tenbury, Worcs in 1914, son of Mr L Ashley, a local solicitor When he Bromsgrove school in 1933 he went to Worcester College, Oxford, where he was awarded a Theodore Williams scholarship for human anatomy He graduated BA with second-class honours in 1936 and won an open scholarship to the Middlesex Hospital He qualified in 1939, taking his medical degree the same year, and volunteered at once for the RNVR, and after holding a house-appointment at Hove General Hospital he was called up three months after the outbreak of war and posted to HM Destroyer *Imogen* In July 1940 he was seriously injured when his ship was sunk by a collision in a fog and after he recovered he held shore appointment at Portsmouth till March of last ye when he was appointed to HMS *Hermione*



Wright & Logan,

Infectious Disease in England and Wales

WEEK ENDED JULY 4

Notifications —The following cases of infectious dis were notified during the week smallpox, 0, scar fever, 1396, whooping-cough, 1457, diphtheria, 72 paratyphoid, 14, typhoid, 4, measles (exclu rubella), 7581, pneumonia (primary or influenzal), 73 puerperal pyrexia, 161, cerebrospinal fever, 10 poliomyelitis, 7, polio-encephalitis, 2, enceph lethargica, 6, dysentery, 242 (100 at Penrith), ophthal neonatorum, 83 No case of cholera, plague or typh fever was notified during the week

The number of civilian and service sick in the Infectious Ho p of the London County Council on July 1 was 1624, includ scarlet fever, 172 diphtheria, 147, measles 410 whoopi cough 298 enteritis 57 chicken pox 77, erysipelas mumps 60 poliomyelitis 1 dysentery 32, cerebrospinal f 11 puerperal sepsis 18 enteric fevers, 4 german measle other diseases (non infectious), 169 not yet diagnosed, 56

Deaths —In 126 great towns there were 1 (0) dea from an enteric fever, 3 (0) from scarlet fever, 5 (1) fr measles, 7 (0) from whooping-cough, 17 (2) from di theria, 30 (2) from diarrhœa and enteritis under t years, and 11 (0) from influenza The figures parentheses are those for London itself

Ilford reported the fatal case of an enteric fever The boro of Heston and Isleworth Liverpool Sunderland and Birming each reported 4 deaths from diarrhœa

The number of stillbirths notified during the w was 227 (corresponding to a rate of 36 per thousand to births), including 20 in London

Letters to the Editor

DOSAGE OF LOCAL ANÆSTHETICS

,—In your last issue Dr Organe put on record the consequences which may follow the use of doses of local anæsthetics He seems himself g to countenance doses which, although much er than the ones used originally, appear to us still cessarily large The makers of 'Percaine' state that maximal therapeutic dose in man is 2–3 mg per ' and on this basis it may not be dangerous to give cm of 1 1000 percaine (i e , 150 mg) to a 10-stone ; but we do know that satisfactory operating itions following intercostal, abdominal or brachial- is block can be obtained with a considerably less itity of 1 2000 or 1 3000 percaine , while for the nsive nerve blocks preceding laryngectomy we use, routine, a total of 60 c cm of 1 2000 percaine for a ent weighing 10 stone—i e , a dosage of ½ mg /kilo or ig

commonly accepted standard for a full dose of aine (synonyms 'Novocain,' 'Planocaine,' 'Sevi- e,' *et al.*), given intrathecally for upper abdominal sthesia in an adult, is 200 mg , for percaine 15 c cm . 1500 dilution—i e , a total of 10 mg From this it be seen that satisfactory anæsthesia is obtained from aine in a twentieth of the dose needed for procaine local anæsthesia 100 c cm of 1% solution of procaine 1 g. of procaine) is commonly taken as a standard dose for an adult A dose of percaine equivalent to would be 50 mg , or a third the quantity of percaine h Dr Organe would be ready to give to a 10-stone

e suggest that for local anæsthesia percaine should ly be used in concentrations exceeding 1 2000 and seldom is a dose in excess of 50 mg necessary

R R MACINTOSH,
ford FREDA B BANNISTER

CONSIDERATE TONSILLECTOMY

R,—In your leading article of June 27 you advocate ting children requiring tonsillectomy as inpatients advantages are obvious , during all the years I was geon in charge of the department at the Bristol Royal rmary I made inpatient treatment my rule But no obvious is the increase in the expense, as compared h outpatient treatment , and a community impover- d by war may well have to consider whether the antage is commensurate When the weather is m, ambulance transport provided, home conditions d, and nursing and if needed medical attendance ilable, the disadvantages of treating the majority of se cases in the outpatient department are not very at , and we may have to decide that beds must be erved for patients whose need is greater As to medication, is it not rather a luxury than strictly essary ? The operation is so common that most ldren come up reassured by experienced comrades t there is nothing to fear—I have long ceased to rvel at their docility in the anæsthetic room Very, y rarely does a child object to examination after the ration or show other signs of having been frightened , l while I can show several cases in which enuresis or ht terrors ceased after operation I do not recall one which they began then

ou mention "the older method," suspected of being her crude The older method is a formal dissection, h volsellum and scissors , some surgeons, I believe, n expect suspension and intratracheal anæsthesia king it definitely a major operation For the occa- al operator this is doubtless the method of choice e modern method is that described by Whillis and bus (*Lancet*, 1910, ii, 875) A very blunt guillotine is d to evert and to hold the tonsil during the dissection , resulting removal is complete and exact, with imal bleeding and no interference with the fascia ering the muscles It demands practice and a certain ack, apparently not readily acquired by those of riper rs, and it is of British origin These drawbacks are weighed by its simplicity, the short time needed, and relative absence of pain after operation , and it has ablished itself as the routine method for those who have to carry out several hundred such operations year after year.

I venture to make this point since we still meet those who, impressed by the often elaborate ritual of volsellum dissection, and perhaps prejudiced by the odium which in the opening years of the century attached to the guillotine (*cf* Hey Groves, E W "The advantages of enucleation of the tonsils over removal by guillotine," *Bristol med-chir J* 1905, 23, 32), fail to appreciate the merits, surgical and economic, of the modern procedure

Bristol 8 E WATSON-WILLIAMS

THE THIRD DIMENSION IN DIAGNOSIS

SIR,—Of two interesting articles which appeared in your columns this year, one (Cook and Sargant, Jan 10, p 31) demonstrated the unfortunate results of mistaking nervous disorders for organic disease , the other (Hulbert, May 23, p 614) showed the unhappy effects of mistaking organic disease for nervous disorder Both were written with proper scientific restraint and relied on the objectivity of case-records to substantiate their separate points of view. Each article solidly proved its case This was perhaps the less difficult in that the truth of both theses was in any event self-evident

I suggest that the real point lies a little deeper In my own area in recent weeks I have come across two cases from EMS hospitals which are typical examples of one side of the question The first was a case of blatant hysteria, with massive areas of analgesia, which was diagnosed, on the basis of a visible pulsation in the neck, as arteriovenous aneurysm of the left innominate artery, and operated upon—no aneurysm being found The second was a case of enuresis with the history and symptomatology of a typical anxiety neurosis, which was treated by excision of the left seminal vesicle on the grounds that it was larger than the right ! It may be added that these instances are by no means exceptional The suggestion I have to make is that such astonishing gaffes are not adequately countered by the production of cases treated with equal folly by psychiatrists The " tu quoque " is always a juvenile rejoinder, even when clothed in statistics Moreover the circumstances are not parallel When a psychiatrist misses the symptom-syndrome of a physical disease for, say, three months, he makes what is admitted by everyone, including himself, to be a serious error , and articles are scarcely needed to prove the liability of human beings to make serious errors But when physicians or surgeons miss a classical case of anxiety neurosis, and investigate it for three months, to its lasting detriment, with every known variety of diagnostic apparatus, they are said to be " eliminating the possibilities of physical disease " It is precisely this attitude that demands an explanation , and admits, I suggest, of only one They are applying a two-dimensional concept to a three-dimensional problem Their efforts resemble those of intelligent two-dimensional creatures striving to comprehend a cube

The psychiatric approach is not solely another department to which certain cases are to be relegated , it also supplies a new and vital factor in *every* case, not alternative to the picture presented by medicine and surgery but enriching that picture by addition of the human perspective The truth is that psychiatry has two aspects Out of the lack of a general recognition of this fact spring most of the futile disputes centring round its function. From one aspect it is indeed a definable specialty of medicine, though not of neurology, with which it has neither more nor less connexion than has neurology with the other specialties. From the other it is itself the offshoot of a new direction of the human mind, a direction discernible in many fields besides our own , and from this aspect it is applicable to every branch of our profession From this latter aspect the psychiatric approach is neither more important nor less important than a new dimension of human measurement, meaningless without reference to the other dimensions, as they, without reference to it, are incomplete Spatially expressed, where medicine is the height and surgery is the length, psychiatry is the depth of the human box of tricks

This concept implies, as relativity did to Newtonian physics, a mental readjustment to matters long considered professionally settled But the older ideas are thereby extended, not dispossessed The apple still falls on the philosopher's head in spite of Einstein, and the knife will continue to fall on the gangrenous appendix in spite of the psychiatric approach Nevertheless, like the picture of the universe, the picture of the sick person is not what it was Something has been added, comparable only to a stereoscopic effect I suggest that the complete acceptance—lacking even in some psychiatrists—of this fundamental reorientation will put an end, in those cases whose neurosis is manifest, to what may be called the laborious elimination of the inherently improbable But it will do more Its inclusion in our normal modes of reasoning will immeasurably enrich the possibilities of therapy, and open up a way for fresh advances of medicine in line with the new direction of thought

Aldershot ? ALAN MCGLASHAN

PHLYCTENULAR OPHTHALMIA

SIR,—The annotation in your issue of July 4 referring to Mr Sorsby's interesting work concludes by mentioning the evidence "that tuberculous infection can act as the sensitising agent of phlyctenular ophthalmia" and in the last sentence states "If so, sufferers from phylctens must be regarded as in a dangerous state of health and needing antituberculous treatment" Pædiatricians have long regarded phlyctens as similar to erythema nodosum—both hypersensitivity phenomena, and frequently tuberculin is the sensitising agent In both instances the practical point is that the child with erythema nodosum or with phlyctens may come from an environment in which an unsuspected case of open pulmonary tuberculosis exists and in every instance a search for such contact should be made I suspect—but my evidence is yet small—that both these hypersensitivity phenomena occur with intermittent, small dosage of infection Children with phlyctens are seldom "in a dangerous state of health" but they may be in a dangerous environment and other members of the family or other children in the same school class (e g, with a tuberculous teacher) may not be so lucky Their dosage may result in tuberculous meningitis or miliary tuberculosis. In my view every child with a phlycten should be tested with 0 1 c cm of 1 to 10,000 old tuberculin If strongly positive to this weak dilution then a tuberculous origin for their eye trouble is highly probable and the search for the source of infection should be energetically pursued

SMELL FROM PLASTERS

SIR,—Professors Seddon and Florey state that when the closed plaster technique is used a practically sterile wound is comparatively rare, thus implying that most open wounds treated in this way become septic Happily most of the wounds reaching us here could be treated by radical excision within six hours of the time of injury During the five months that I have been attached to this accident service I have not seen a pus-soaked plaster among fifty-odd cases admitted with open wounds treated by closed plaster, and I have known only one wound to become septic The smell that does emanate from the plaster is that of dried blood and has not aroused comment except in two cases, neither of which needed interference

SOLDIER'S DOCTOR

SIR,—Your leader makes one wonder whether the writer has ever been a regimental MO or has merely read about it in books Let him lay aside his rose-coloured spectacles for a moment and consider the facts "The task of keeping a thousand men fit" would, I agree, be a fascinating one if the MO had the same thousand men under his professional care for any length of time, but the snag is that the men—and the MO—are always liable to be moved elsewhere at short notice, thus, there is no security of tenure, no permanency in the doctor-patient relationship As for "the great variety of practice," it simply does not exist, the types of illness and injury seen (when not in action) are extremely limited in range and, if anything of real interest crops up, the patient is forthwith admitted to a hospital often a long way away so that the MO must lose sight Moreover, on discharge from hospital, the pa like as not posted to another unit and so passes MO's ken for ever It is true that, within narrow there is scope for preventive medicine, but the MO takes an undue interest in trivial illnesses will soon his sick parades growing in numbers, which is frowned upon by the combatant authorities " and confidence" in the soldier are best main discouraging him from making a fuss Of hospitals I know nothing, but I would be grateful for list of these mysterious ailments which can be " in the bud" It is idle to deny that the job of re MO is conducive to apathy Many MO's become bored that they will not even attend refresher arranged for them unless compelled to do so It is the strongest spirits who can maintain their and energy in such circumstances When the unit action, of course, it is quite another matter

Crediton, Devon L N JACKSON

A THOUSAND YEARS OF ŒSTRIN THERAP

SIR,—Endocrine treatment is generally considered advance of the last forty years or so While the direct experimental evidence for the existence of secretions of any kind was furnished by Berthold 1849 by means of testicular transplants in animals, endocrine extracts were advocated in the ninete Brown-Séquard for rejuvenation, it was only in that the first successful transplantation for purposes was carried out by Morris with ovarian and the potency of organ extracts was not scie demonstrated until 1912 when Alder induced mice by means of aqueous ovarian extracts

Œstrin therapy, however, was practised in the century Going through "Ortus Sanitatis," an pharmacopœia by an unknown author, first pub 1494 by Jacobus von Meydenbach in Germany, I struck by a quotation from "Haly" Fimus equ vaporietatis fœtuos mortuum mulieri fecundinam (The excrement of horses when evaporated brings the delivery of dead fœtuses of a pregnant w *NB*—The bad Latin is original) The Persian, ben Abbas, who died in A D 994, was court physician the Buwide Emir Adhad ad-Daula and dedicated to ruler under the title "Al-Maliki" (The Royal Book) work which was the canonical treatise on medicine for century until it was superseded by Avicenna's Translated into Latin in 1080 by Constantinus it went through a series of editions, the principal being the Venetian of 1492 and that of Lyon of 15

The empirical use by Haly ben Abbas of eva horse's urine for inducing stillbirth is interesting in light of the recent discovery of Zondek that the urine pregnant mares and stallions is one of the richest so œstrin available, and the work of Knaus showing that the oxytocic principle of the posterior pituitary is to on the uterus, the latter must have been pre sensitised with large doses of œstrin

Oxford PETER P H SCHMIDT

REACTIONS TO THE REPORT

SIR,—The planning of the future health services a state of complete confusion The BMA P Commission in its interim report rejects state m in a state-salaried service The Medical Practi Union is endeavouring to formulate a state medical for approval by the Government The National H Association (headquarters at Tunbridge Wells) is pl a local government scheme administered by committees Doubtless many others are also p schemes Before going any further the Gov should state, without any equivocation, what it us to plan This is essential, since it either will or not cover two professional imponderables—freedom choice of doctor and patient, and compensation for invested in practices The second must be cl before any steps can be taken As I see the either the Government has not said what it wants or planning commission has kept the wishes of the Go ment from the profession. Probably a full state was put up to the commission by the Government they would not have plann ection The ssion should have been given the opportunity of g on it before the commission rejected a full state e It may be asked whether the MPU have com- with governmental wishes or instructions in en- ouring to formulate plans for a full state service, whether the planning commission, with or without backing of a majority of the profession, rejected wishes of the Government If so the commission wait to find out the reactions of the Government e doing any further planning Again I ask, what ve supposed to be planning?

Notes and News

PLAN OR NO PLAN?

as seems likely, research will be supported more and by public money it is well for the public to under- how to ensure a good return for their money. In ast, of course, the support has been quite inade- , thus J. D Bernal[1] estimates that, in 1934, gross amount spent by Government on medical rch was £150,000, probably less, he adds, than a of what would be reasonable and desirable in any sed country But a more lavish expenditure can elcomed only if it goes hand in hand with wise nistration, and the use of the products of research e common good Dr Alan Gregg,[2] who is director nedical sciences at the Rockefeller Foundation, ore than doubtful about short-term policies in the ing of research Far better to endow institutes laboratories well, for it is notoriously difficult to gnise research ability at an early stage A short- grant might give the aspirant a period of probation uch to establish a claim to more permanent support; much money is squandered in this way, and it might ise to test a would-be researcher by other means— xample, as an apprentice or student assistant to some e seasoned worker in medical school or university levote funds solely to research which seems to be of tical use is futile, as both Gregg and J R Baker[3] t out Baker, scenting danger in "planning" and e control, urges that the researcher must have com- e liberty to pursue his work without political influence aterference Few would wish to dispute his belief , "in science there is no loyalty to creed, party or only to demonstrable truth and reason" But dread of an approaching state dictatorship over the jects and methods of research seems unfounded, egin with, any such tyranny could only be achieved he cost of revolutionary changes in the present con- t and policy of the Medical Research Council, and many important discoveries have been made by vidual workers that they may well claim the right ursue their ways undisturbed But as an inevitable lt of growing specialisation, there is growing room team-work too, especially when the research is well nned and the members of the team have combined, as a result of outside pressure, but by mutual consent

A DOUBLE STETHOSCOPE

HE Bin-Aural Comparator manufactured by the ac Company (2 Ullswater Road, London, S W 13), useful, if massive, form of stethoscope which makes ossible to compare simultaneously the sounds over two areas of the lungs or heart The two chest es, made of aluminium alloy, each consist of a special ular diaphragm contained in a small chamber to which either a conical or a concave end-piece can be attached The head frame is a self-adjusting model which can be fixed in any desired position by means of a milled clamping nut The instrument has the additional advantage that it can be converted into an ordinary type of stethoscope It transmits respiratory and heart sounds satisfactorily without distortion, but there may be some who will find difficulty in analysing the sounds transmitted to the ear simultaneously from two different areas of the chest

Royal College of Surgeons of England

At a meeting of the council held on July 9, Sir Alfred Webb-Johnson was re-elected president and Surgeon Rear-Admiral Gordon-Taylor and Mr L R Braithwaite vice presidents

The following were elected for the ensuing year

Hunterian professors—Mr W H Bowen etiology of acute appendicitis, Mr H T Roper Hall, premaxillary cysts, Dr L H Savin, surgery of non magnetic intraocular foreign bodies, Mr J Cosbie Ross, injuries of the urinary bladder, Dr Raymond Greene, frostbite and kindred conditions, Mr S M Cohen, traumatic arterial spasm Mr J. E A O'Connell, vascular factor in the cerebrospinal fluid circulation and its relationship to intracranial pathological processes, Mr O. S Tubbs, effect of ligation on infection of the patent ductus arteriosus, Mr Alexander Weddell, cutaneous innervation, and Mr W Bremner Highet, injuries to peripheral nerves

Arris and Gale Lecturer—Prof H A Harris, anatomy of posture in industry clinical anatomy of the veins and relation of the lymphatic system to the arterial and venous systems

Erasmus Wilson Demonstrators—Mr L E C Norbury, Mr R Davies Colley, Mr C E Shattock, and Mr C P G Wakeley

Arnott Demonstrator—Dr A J E Cave

Sir Frank Colyer was re appointed honorary curator of the odontological collection The thirteenth Macloghlin scholarship was awarded to J A G Holt, of Bristol Grammar School, and Miss H B Collard, BA, was re appointed a Leverhulme scholar for a further year

It was decided to recognise the posts of senior house-surgeon and first assistant house surgeon at the Essex County Hospital, Colchester, for the six months' surgical practice required of candidates for the final fellowship examination and to renew the recognition of the post of house surgeon at the Walsall General Hospital for the duration of the war

A diploma of fellowship was granted to R S Lawrie, MB Lond, MRCP, and a diploma of membership to J. A Judson (Leeds) The following diplomas were granted jointly with the Royal College of Physicians·

D P H—Raghunath Bhaskar, P R T Naidu, William Dodd

D P M—J F Cooper, Harry Fleming, Gerald Garmany, Margaret J Garmany, J H Gould, Samuel Leviten, Patrick Morris, John Slorach and P C C Tresise

A THOUSAND YEARS OF ŒSTRIN THERAPY

SIR,—Endocrine treatment is generally considered an advance of the last forty years or so While the first direct experimental evidence for the existence of internal secretions of any kind was furnished by Berthelot in 1849 by means of testicular transplants in animals, and endocrine extracts were advocated in the nineties by Brown-Séquard for rejuvenation, it was only in 1895 that the first successful transplantation for clinical purposes was carried out by Morris with ovarian tissue, and the potency of organ extracts was not scientifically demonstrated until 1912 when Alder induced œstrus in mice by means of aqueous ovarian extracts

Œstrin therapy, however, was practised in the 10th century Going through " Ortus Sanitatis," an old pharmacopœia by an unknown author, first published in 1494 by Jacobus von Meydenbach in Germany, I was struck by a quotation from " Haly " Fimus equorum si vaporietatis fœtuos mortuum mulieri fecundinam educit (The excrement of horses when evaporated brings about the delivery of dead fœtuses of a pregnant woman *NB*—The bad Latin is original) The Persian, Haly ben Abbas, who died in A D 994, was court physician to the Buwide Emir Adhad ad-Daula and dedicated to that ruler under the title " Al-Maliki " (The Royal Book) a work which was the canonical treatise on medicine for a century until it was superseded by Avicenna's Canon Translated into Latin in 1080 by Constantinus Africanus it went through a series of editions, the principal ones being the Venetian of 1492 and that of Lyon of 1529

The empirical use by Haly ben Abbas of evaporated horse's urine for inducing stillbirth is interesting in the light of the recent discovery of Zondek that the urine of pregnant mares and stallions is one of the richest sources of œstrin available, and the work of Knaus showing that, if the oxytocic principle of the posterior pituitary is to act on the uterus, the latter must have been previously sensitised with large doses of œstrin

St Catherine's Society,
Oxford PETER P H SCHMIDT

REACTIONS TO THE REPORT

SIR,—The planning of the future health services is in a state of complete confusion The BMA Planning Commission in its interim report rejects state medicine in a state-salaried service The Medical Practitioners Union is endeavouring to formulate a state medical service for approval by the Government The National Health Association (headquarters at Tunbridge Wells) is planning a local government scheme administered by insurance committees Doubtless many others are also planning schemes Before going any further the Government should state, without any equivocation, what it wants us to plan This is essential, since it either will or will not cover two professional imponderables—freedom of choice of doctor and patient, and compensation for capital invested in practices The second must be cleared up before any steps can be taken As I see the position either the Government has not said what it wants or the planning commission has kept the wishes of the Government from the profession Probably a full state service was put up to the commission by the Government, or they would not have planned its rejection The whole profession should have been given the opportunity of voting on it before the commission rejected a full state service It may be asked whether the MPU have complied with governmental wishes or instructions in endeavouring to formulate plans for a full state service, and whether the planning commission, with or without the backing of a majority of the profession, rejected the wishes of the Government If so the commission must wait to find out the reactions of the Government before doing any further planning Again I ask, what are we supposed to be planning ?

MEDICAL DIRECTORY 1943

SIR,—To maintain the accuracy of our annual volume we rely upon the return of our schedule, which has been posted to each member of the medical profession Should the schedule have been lost or mislaid we will gladly forward a duplicate upon request The full names of the doctor should be sent for identification

104, Gloucester Place, W 1 J & A CHURCHILL Ltd

Notes and News

PLAN OR NO PLAN?

IF, as seems likely, research will be supported more and more by public money it is well for the public to understand how to ensure a good return for their money In the past, of course, the support has been quite inadequate, thus J. D Bernal[1] estimates that, in 1934, the gross amount spent by Government on medical research was £150,000, probably less, he adds, than a tenth of what would be reasonable and desirable in any civilised country But a more lavish expenditure can be welcomed only if it goes hand in hand with wise administration, and the use of the products of research for the common good Dr Alan Gregg,[2] who is director for medical sciences at the Rockefeller Foundation, is more than doubtful about short-term policies in the planning of research Far better to endow institutes and laboratories well, for it is notoriously difficult to recognise research ability at an early stage A short-term grant might give the aspirant a period of probation in which to establish a claim to more permanent support; but much money is squandered in this way, and it might be wise to test a would-be researcher by other means—for example, as an apprentice or student assistant to some more seasoned worker in medical school or university To devote funds solely to research which seems to be of practical use is futile, as both Gregg and J R Baker[3] point out Baker, scenting danger in "planning" and state control, urges that the researcher must have complete liberty to pursue his work without political influence or interference Few would wish to dispute his belief that "in science there is no loyalty to creed, party or class only to demonstrable truth and reason" But his dread of an approaching state dictatorship over the subjects and methods of research seems unfounded, to begin with, any such tyranny could only be achieved at the cost of revolutionary changes in the present conduct and policy of the Medical Research Council, and so many important discoveries have been made by individual workers that they may well claim the right to pursue their ways undisturbed But as an inevitable result of growing specialisation, there is growing room for team-work too, especially when the research is well planned and the members of the team have combined, not as a result of outside pressure, but by mutual consent

A DOUBLE STETHOSCOPE

THE Bin-Aural Comparator, manufactured by the Capac Company (2 Ullswater Road, London, S W 13), is a useful, if massive, form of stethoscope which makes it possible to compare simultaneously the sounds over any two areas of the lungs or heart The two chest pieces, made of aluminium alloy, each consist of a special annular diaphragm contained in a small chamber to which either a conical or a concave end-piece can be attached The head frame is a self-adjusting model which can be fixed in any desired position by means of a milled clamping nut The instrument has the additional advantage that it can be converted into an ordinary type of stethoscope It transmits respiratory and heart sounds satisfactorily without distortion, but there may be some who will find difficulty in analysing the sounds transmitted to the ear simultaneously from two different areas of the chest

Royal College of Surgeons of England

At a meeting of the council held on July 9, Sir Alfred Webb-Johnson was re elected president and Surgeon Rear-Admiral Gordon-Taylor and Mr L R Braithwaite vice-presidents

The following were elected for the ensuing year

Hunterian professors—Mr W H Bowen, etiology of acute appendicitis, Mr H T Roper-Hall premaxillary cysts, Dr L H Savin, surgery of non-magnetic intraocular foreign bodies, Mr J Cosbie Ross injuries of the urinary bladder, Dr Raymond Greene, frostbite and kindred conditions; Mr S M Cohen, traumatic arterial spasm Mr J E A O'Connell, vascular factor in the cerebrospinal fluid circulation and its relationship to intracranial pathological processes, Mr O S Tubbs, effect of ligation on infection of the patent ductus arteriosus, Mr Alexander Weddell, cutaneous innervation, and Mr W Bremner Highet, injuries to peripheral nerves

Arris and Gale Lecturer—Prof H A. Harris, anatomy of posture in industry clinical anatomy of the veins and relation of the lymphatic system to the arterial and venous systems

Erasmus Wilson Demonstrators—Mr L E C Norbury, Mr R. Davies Colley, Mr C E Shattock, and Mr C P G Wakeley

Arnott Demonstrator—Dr A J E Cave

Sir Frank Colyer was re appointed honorary curator of the odontological collection The thirteenth Macloghlin scholarship was awarded to J A G Holt, of Bristol Grammar School, and Miss H B Collard, BA, was re appointed a Leverhulme scholar for a further year

It was decided to recognise the posts of senior house-surgeon and first assistant house surgeon at the Essex County Hospital, Colchester, for the six months' surgical practice required of candidates for the final fellowship examination and to renew the recognition of the post of house-surgeon at the Walsall General Hospital for the duration of the war

A diploma of fellowship was granted to R S Lawrie, MB Lond, MRCP, and a diploma of membership to J. A Judson (Leeds) The following diplomas were granted jointly with the Royal College of Physicians.

D P H—Raghunath Bhaskar, P R T Naidu, William Dodd

D P M—J F Cooper, Harry Fleming, Gerald Garmany, Margaret J Garmany, J H Gould, Samuel Leviten, Patrick Morris, John Slorach, and P C C Tresise

D.L O—J A. Harpman, C M Johnston, Ernest Kaplan, E C Richardson, and Ernst Rosenbaum

University of Aberdeen

On July 9, the following degrees and diplomas were conferred:

M.D—A H Cruickshank (*in absentia*) with highest honours, and D A Hunter, with commendation

M.B, Ch B—A L C Stalker (with first-class honours), John Mowatt (with second-class honours), Alexander Adam, Mary R Alexander, R. M Allan, Edwin Anderson, R M L Anderson, H I C Bowie Inez M Brebner D D Brown, I M Brown, A P Buchan, I J Buchan, Mary S Buchan, Neil Budge, James Cantlie, T L Carr, J R W Catto, Isabel M. S Chalmers, I G L Craig, J L T Dickie Margaret S Duguid, D M Dunbar, Lorna L Duncan, Eileen M Duthie, G W Forbes, Helen S Fraser, Leslie W. Fraser, W G French, Robert Gibb, Isobel R Grattidge, John Gray, A M Gwynn, Muriel O Henderson, G L Herbert, Eilean A Hunter, J G Hunter, T O'N F. Kelly, Margaret C Kemp W Y Laidlaw, Agnes K Leslie, J C Lightbody, R K MacCuish, J C M MacDonald, W H McGillivray, W B McGowan, Dorothy J Mackay, J M McKay, A A. Mackie, A H McLaren, Mary E C Maclean, Muriel M McLean Alexander Mair, V D R Martin, Elza H. Meadows D G Milne, J G Murray, Cecilia M Park G M. Reid, Alma O Ritchie, Mary B Robb, A. F Ross, G I M Ross, K A. D Ross, I L Roy, L S Rusack J K Russell, A G Scott, G M Sinclair, Emily S Smith, E B Smith, J A E Stewart A. B Strachan, Cecilia V Urquhart, Andrew Walker, S J. M Walker, W A Walker, William Watt, Dorothy M A White, G A Wilson, and J H Wood.

D.P.H—Mary Anderson, C T Baynes, Enid M Clow, and Vera D Davidson

University of Bristol

At recent examinations the following were successful.

FINAL EXAMINATION FOR M B, CH.B

G H Valentine and G H Wattley (with second class honours), Nancy R. Baldwin, R F Brooks, Rosalie M Child, D G Davies, John Deighton, G F M Hall, Joyce Kennard A G H Mitchinson, E W Moore J L Pardoe A R Rowe, Norman Slade, M. H Thomas, Jean Wallace and G A Walton

In Group II (*completing the examination*)—K L Brown and A H M Oakes

Medical Casualties

The following casualties have lately been announced

Death on Active Service—Acting Brigadier Francis Gerald Augustus Smyth, CBE, MB Lond, late RAMC

Missing, presumed killed—T/A/Surgeon Lieut Commander Harold Theodore Logan Broadway, MRCS, RNVR, HMS *Dunedin*, T/Surgeon Lieutenant William Anthony Cavanagh, LRCPI RNVR, HMS *Repulse*, and Surgeon Commander Douglas Arnold Newbery, MRCS, RN, HMS *Repulse*

Prisoners of War—Major D C Bowie, FRCSE, RAMC, Major E J Curran, MB NUI, RAMC, WS/Captain R L Lancaster, MB Camb, RAMC, Major H G G Robertson, MRCS RAMC, Captain J E C Robinson, MRCS, RAMC, and Major J E Sawyer, MRCS, RAMC

Country Branch for the London Hospital

A self contained hutted hospital which has been built in the grounds of an LCC children's hospital in Essex will be staffed and run by the London Hospital, some of the 360 beds being reserved for EMS cases In three years over 51,000 beds have been built by the Ministry of Health under the Emergency Hospital Scheme

Medical Society for the Study of Venereal Diseases

The annual general meeting of this society will be held at 11, Chandos Street, London, W 1, on Saturday, July 25, at 2 P M At 2 30 P M Mr Aleck Bourne will read a paper on the diagnosis and treatment of non-gonococcal vaginal discharges

Socialist Medical Association

At a meeting on Wednesday, July 22, at 7 30 P M, at the Conway Hall, Red Lion Square, London, W C 1, Mr B C J G Knight, D Sc, will speak on the sulphonamides some history and theory

Maternity and Child Welfare Group

About eighty doctors attended the third refresher course held by this group of the society of MOHs which took place at Gt Ormond Street Hospital on July 4, when Dr Donald Paterson spoke on premature babies and feeding difficulties, and Mr Denis Browne on orthopaedics with special reference to minor degrees of deformity

In his paper on disorders in infancy, Dr Wilfrid Sheldon laid stress on the conditions found by medical officers in their work at the welfare centre sessions, and Dr W G Wyllie's lecture on the work of an asthma clinic was followed by a demonstration of skin tests, radiograms and breathing exercises

Personnel for Tuberculosis Institutions

On June 22 a deputation on the shortage of nursing and domestic personnel in tuberculosis institutions was received at the Ministry of Health by Sir Wilson Jameson, chief medical officer, Mr J C Wrigley, deputy secretary, Sir Weldon Dalrymple Champneys, deputy CMO, and Miss K Watt, chief nursing officer

The deputation, which consisted of Dr D A Powell, Dr D P Sutherland, and Dr J B McDougall (Joint Tuberculosis Council), Dr G T Hebert and Dr H G Trayer (Tuberculosis Association), Captain G S Elliston, M P (Society of MOHs), Sir Percival Horton Smith Hartley, Dr R A Young, Dr F R G Heaf and Dr Harley Williams (NAPT), considered the shortage to be due to fear of infection and lack of glamour in nursing tuberculous patients in comparison with service casualties It was urged that the Minister of Health should release himself from the pledge given to the Civil Nursing Reserve that its members should not be required to work in sanatoria unless they volunteered specially, and that a uniform scale of salaries should be set up

Stretchers for Merchant Ships

The joint advisory committee on the health of the cantile Marine has recommended that at least two Robertson stretchers shall be carried in all foreign g merchant ships A description of this stretcher appeare our columns last year (*Lancet*, 1941, i, 289)

Queen's Institute of District Nursing

During 1941 Queen's nurses and village nurse midw attended 87,906 confinements with 136 (or 1 6 per 1 maternal deaths There are now 1543 Queen's nurses 2752 nurse midwives

Royal Society of Tropical Medicine and Hygiene

The annual general meeting will be held at 26, Portl Place, London, W 1, on Thursday, July 23, at 4 30 Afterwards Sir Rickard Christophers, FRS, will read a p on the treatment of malaria

---

FIRST AID posts and mobile units are being issued hydrogen peroxide (20 vols) for the treatment of Lew burns and with dredgers containing sulphanilamide pov for dusting on wounds when there is likely to be delay getting a casualty to hospital In future morphia will kept at the posts in 1 oz or ½ oz bottles containing g morphine sulphate per c cm

Mr W S GORDON, Ph D, has been appointed directo the field station of the Agricultural Research Council Compton, near Newbury, Berks, in succession to the Mr G W Dunkin Dr Gordon has been senior bacteriolo on the staff of the Animal Diseases Research Associatio Moredun Institute, Gilmerton, Midlothian, since 1930

The fact that goods made of raw materials in s supply owing to war conditions are advertised in paper should not be taken as an indication that they necessarily available for export

Appointments

TURNER, C E H, MRCS, DPH deputy medical superintenden the City Mental Hospital, Leicester
SMITH, D MORRISON, MB EDIN temp clinical TO for West Nor
PARMITER, B R, MB LOND examining factory surgeon Wimborne, Dorset

Births, Marriages and Deaths

BIRTHS

BUTLER—On July 4, at Farnham, Surrey, the wife of Dr Ken A. Butler—a daughter
CLYNE—On July 2, at Edinburgh, the wife of Dr Dougla Wilson Clyne—a daughter
COOKSON—On July 7, at Bournemouth, the wife of Dr Ha Cookson—a son
CRADDOCK—On July 8, at Woking, the wife of Surgeon Lieute J G Craddock, RNVR—a son
GOLD—On July 6, at Stansted, Essex, the wife of Lieute Stephen Gold, RAMC—a daughter
FALK—On July 6, at Warminster, the wife of Captain John RAMC—a son
GRAY—On July 6, in London, the wife of Major Charles RAMC—a son
TOLHURST—On July 9, at Cheam, Surrey, the wife of Sur Lieutenant D A Tolhurst, RNVR—a son
TURQUET—On July 11, the wife of Captain Pierre Turquet, RA a son.

MARRIAGES

ADAMSON—THORPE—On July 7, at Rye, James W W Adam MD, to Marjorie E W Thorpe
FARQUHAR—MARTIN—On July 6, at Kidderminster John B Farquhar, MB, captain RAMC, to Elizabeth Thomson Martin, MB
HOBBS—DANNATT—On July 4, at West Norwood, Frank E Ho MRCS, to Peggy H Dannatt, SRN

DEATHS

BATTEN—On July 9, George Beckett Batten MD EDIN, DMRE, of Dulwich, aged 81
CAMPBELL—On July 12, at Bath, Basil Patrick Campbell CAMB, FRCSE
PATERSON—On July 7, in London, Thomas George Ferg Paterson, CB, DSO, MB DUBL, Major General IMS, retd, la Aldeburgh, Suffolk, aged 65
POWER—On June 27, at Ashby de la Zouche, Edward Th Power, MRCS, of Atherstone, aged 87
TRESIDDER—On May 1, at Antibes, France, Percy Edgar Tresi MRCS, formerly of Nottingham, aged 68
WORTHINGTON—On July 8, at Llandrindod Wells, George Worthington, MB CAMB

FIBRIN SUTURE OF HUMAN NERVES

H J SEDDON
D M OXFD, F R C S
NUFFIELD PROFESSOR OF ORTHOPÆDIC SURGERY IN THE UNIVERSITY OF OXFORD

P B MEDAWAR
M A OXFD
FELLOW OF MAGDALEN COLLEGE, OXFORD

(*Illustrations on Plate*)

IMPROVEMENTS in the material used for nerve suture are of two kinds—a suture material may be discovered of such a composition that it offers little or no obstruction to regeneration, or, on the other hand, it may differ little in this respect from standard suture materials but be advantageous because of ease of application The first gain is biological, the second technical

Since the war of 1914–18 it has come to be fairly clearly understood that certain suture materials are less irritating than others and the irritation produced is proportional to absorbability, a fact first clearly demonstrated by Sargent and Greenfield (1919) There are three fine materials of fair tensile strength and low absorbability—linen and silk thread, and human hair (L Guttmann)—all of which have proved satisfactory A noteworthy advance was the realisation that the suture material should be passed only through the sheath of the nerve for when suture is performed in this way the cellular reaction around the stitches is very nearly extraneural, so much so that unless highly irritating material such as chromicised catgut is used the success of suture (considered only in relation to the operation of bringing the nerve stumps together) depends in the main on the skilful employment of any thread that can be relied on to bring the nerve sheaths together with accuracy It seems, therefore, that further improvements in nerve suture can be only technical, that is to say, simplification of operative manipulation

It will be recalled that when Young and Medawar (1940) introduced a coagulable plasma for the suture of peripheral nerves they were concerned entirely with the repair of small nerves in experimental animals, nerves so small that suture of the sheath was impossible, any stitches used had of necessity to traverse the substance of the nerve It is clear then that the absence of intraneural disturbance after fibrin suture in experimental animals is not of comparable significance in man since the intraneural reaction following through-and-through suture of the small nerves of rabbits does not occur after the perineural suture of human surgery The success of fibrin suture was also dependent on its application to lesions that were in the main recent, there was not the loss of substance which is so constant a feature of the secondary sutures that form the bulk of peripheral nerve repairs performed in man Lastly, the plasma was easy to apply because they always worked in a small field from which the plasma did not tend to drain away

APPLICATION IN HUMAN CASES

Fresh injuries—It has been our misfortune to deal with only four cases of recent division of a human nerve, and in only one of them were conditions suitable for the employment of fibrin suture

On Oct 19, 1940, a man was admitted with a deep and dirty laceration at the wrist which had divided all the flexor tendons, ulnar and median nerves, and both arteries Operation was performed six hours after the injury and apart from being exceedingly tedious was uneventful It was necessary to suture the ulnar nerve with silk because it was divided at an inconvenient point just proximal to the pisiform, where a suitable pool for reception of the plasma could not be improvised (we learned more later about how to fashion such pools) When all the tendons had been sutured the ends of the median nerve were approximated, this could be done with great accuracy because only the smallest quantity of nerve substance required removal Flexion of the wrist and lifting up of the skin edges produced a little pool at the bottom of which lay the median nerve with its cut surfaces in perfect apposition Plasma was dropped into the pit and held the nerve most securely When viewed through the transparent jelly the line of division was almost invisible The wound was closed in the usual way, and the wrist fixed by plaster in 30° flexion It is hardly necessary to record the after treatment in detail Recovery is occurring well in both median and ulnar nerves, and the photograph (fig 1) shows that on the sensory side there is no significant difference in the rate of recovery in the two areas This is what one would expect

The ease with which fibrin suture was performed in this case leads us to believe that the method is ideal for repair of recent nerve injuries—provided that wide resection of the stumps does not have to be performed

Secondary sutures—Apart from two cases of recent partial division, and those in which grafting was necessary (see below), the remainder of our patients with divided nerves required secondary suture The characteristics of the stumps presented for suture after resection has been performed are as follows

There is always a considerable gap, and, although the various measures now available for the mobilisation of nerve trunks make possible the closure of quite large gaps (15 cm in the main trunk of the sciatic nerve, 12 cm in the median, 12 cm in the ulnar and 8 cm in the radial), it cannot be denied that at the final approximation a certain amount of tension is often present, and plasma will not hold nerve ends together under more than the very slightest tension Furthermore the approximation of resected stumps has often to be performed in unnatural positions, the stumps may come together over the surface of a muscle belly—the ulnar nerve, for example, may lie on the surface of the common flexor origin at the elbow—and in a few cases we have had to suture nerves in mid-air, in particular the peroneal or tibial near the knee, and the reposition of the skin flap over the aerial cable has been a most ticklish affair In such cases where mechanical difficulties are great plasma is of no value

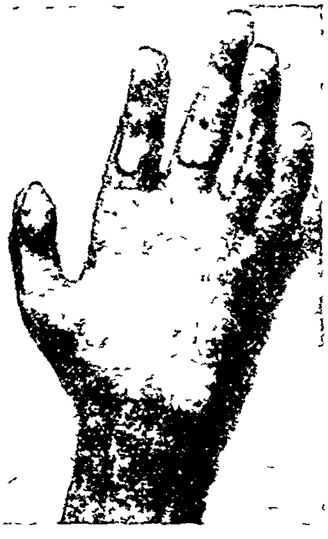

FIG 1—Sensory recovery eleven months after primary suture of median nerve (fibrin) and ulnar nerve (silk) In view of the fact that the ulnar nerve was divided 1 cm distal to the median the difference between ulnar and median sensory recovery is negligible Complete line = touch Dots = pain Dark staining = sweating

Another important feature of the resected stumps is the difference in diameter of central and peripheral cut surfaces, a difference that is roughly proportionate to the time that has elapsed between the injury and the suture Sometimes the diameter of the peripheral stump may be only two-thirds that of the proximal It has been said that this disparity can be compensated to some extent by oblique section of the peripheral stump so as to present an oval surface on the peripheral side having its long diameter equal to the diameter of the circular surface on the central In our experience this has never been possible So it is at once evident that the best hope of obtaining the least unsatisfactory regeneration lies in bringing the proximal and peripheral sheaths together and so preventing the sprouts from the central bundles shooting out laterally and missing the peripheral stump altogether In every case where this disparity in size of the stumps is considerable, reasonably good closure of the sheath can be brought about only by the most careful stitching together of the central and peripheral sheaths, and plasma by itself is of no use

The third characteristic of the stumps at secondary suture concerns the retractility of the nerve sheaths Whenever a peripheral nerve is divided the sheath retracts so that the bundles stick out like those in an electric power cable In some old-standing nerve lesions coming to secondary suture this retraction of the sheath is very striking and sufficient to increase the technical

PULMONARY TUBERCULOSIS IN SERVICEMEN ANALYSIS OF 300 CASES

J H CRAWFORD, M.D LEEDS
ASSISTANT MEDICAL DIRECTOR OF A SANATORIUM

(*Illustrations on Plate*)

THE following analysis of 300 consecutive cases of ulmonary tuberculosis among servicemen admitted to ospital in the past few months may serve to indicate the alue or otherwise of the methods at present used by he recruiting medical boards in recognising such cases at he time of enlistment

The age-groups of the 300 cases investigated were

	Cases		Cases
Under 19	20 (6 6%)	30–39	64 (21 3%)
20–29	202 (67 3%)	Over 40	14 (4 8%)

Forty-two (14%) were cases of pleural effusion in which there was no demonstrable pulmonary lesion, though in 12 of these tubercle bacilli were ultimately found in the luid The remaining 258 (86%) were cases with definite parenchymatous lesions, and subdividing this latter group according to the Ministry of Health classification of TB minus and TB plus (groups 1, 2 and 3), there were

	Cases		Cases
TB minus	40	TB plus, group 2	166
TB plus, group 1	33	„ group 3	19

Not all the TB minus group could be regarded as early or minimal cases, and using the American classification of minimal, moderately advanced and far advanced lesions the grouping was

1 *Minimal lesion*—i e, slight infiltration without demonstrable cavitation, involving a small part of one or both lungs Total volume of lung involved, regardless of distribution, shall not exceed the volume of lung tissue which lies above the 2nd chondrosternal junction and the spine of the 4th or body of the 5th thoracic vertebra on one side 64
2 *Moderately advanced lesion*—i e, one or both lungs involved, total involvement not exceeding the following limits · (*a*) *slight* disseminated infiltration or fibrosis extending through not more than the equivalent of the volume of one lung, (*b*) *severe* infiltration, with or without fibrosis, extending through not more than the equivalent of one third the volume of one lung, (*c*) any gradation within the above limits, (*d*) total diameter of cavities, if present, should not exceed 4 cm 170
3 *Far advanced lesion*—i e, a lesion more extensive than under moderately advanced, or with definite evidence of greater cavity formation 24

Thus, of the parenchymatous lesions, only 24% had minimal disease, 66% had moderately advanced disease and 10% had advanced disease Table I correlates the age-groups with the type of lesion and stage of disease

TYPE OF LESION AND STAGE OF DISEASE AT DIFFERENT AGES

Age (yr)	Lesion				Total
	Effusion only	Parenchymatous disease			
		Minimal	Moderate	Advanced	
Under 19	4	7	7	2	20
20–29	37	27	126	12	202
30–39	1	25	30	8	64
Over 40	0	5	7	2	14
Total	42	64	170	24	300

A significant history, as detailed below, was given by 48 (16%) of the men In only 4 cases, however, was a further opinion sought by the recruiting board, and even then no X-ray examination of the chest was done

Previous stay in sanatorium	8*
Family history of tuberculosis	10
History of pleurisy	9†
History of winter cough or bronchitis	15‡
History of hæmoptysis	6

* Not disclosed in 4 cases, other 4 were regarded by the board as quiescent or arrested after further details had been given by the tuberculosis officers acquainted with the cases

† Including 1 case with family history of tuberculosis

‡ Including 2 cases with family history of tuberculosis and 1 with history of pleurisy

MODE OF ONSET

In more than 70% of the cases the mode of onset was insidious, and a classification of the primary symptoms shows the following incidence.

	Per cent		Per cent
Cough	39	Pleurisy	5
Pleural effusion *	23	Gastro intestinal symp	4
Lassitude	12	Shortness of breath	3
Hæmoptysis	10	Persistent laryngitis	3

* Effusion alone, 14%, effusion with underlying parenchymatous disease, 9%

In the remaining 1% the lesion was discovered at a special examination for service abroad

The majority of cases were sent by the battalion medical officer for further investigation without undue delay, and on the whole medical officers appear to be fully alive to the early symptoms of tuberculosis, though sporadic cases are still met where men have been retained on duty without an X-ray examination of the chest despite the persistence of suggestive symptoms

DURATION OF SERVICE

Analysing the duration of service before the onset of definite symptoms (table II) it is seen that nearly three-quarters of the men had less than a year's service, and in 8% of the cases the diagnosis was made within 3 months of enlistment

TABLE II—DURATION OF SERVICE

Group	1	2	3	4	5
Duration of service	Less than 1 month	1–3 months	3–6 months	6–12 months	Over 1 year
No of cases	4	20	38	152	86

Further analysis showed that, in group 1, one patient was a case of pleural effusion and had a bad family history of tuberculosis, the remaining 3 men had advanced lesions, one of them giving a history of hæmoptysis 5 months previously

In group 2 there were 3 cases of pleural effusion, one man having a family history of tuberculosis and the other 2 having both had previous attacks of dry pleurisy Of the 17 cases with parenchymatous lesions, 2 had a family history of tuberculosis, 3 had a suggestive previous history and 1 had previously been in a sanatorium

TABLE III—CORRELATION BETWEEN TYPE OF LESION, DURATION OF SERVICE AND SUGGESTIVE FACTORS IN MAN'S HISTORY

Duration of service in months	Cases with pleural effusion					With parenchymatous disease				
	Family history of TB	Previous san treatment	Significant personal history	Clear family and personal history	Total	Family history of TB	Previous san treatment	Significant personal history	Clear family and personal history	Total
Less than 1	1				1			1	2	3
1–3	1		2		3	2	1	3	11	17
3–6	1			9	10	2	4	16	6	28
6–12	1			15	16	1		3	132	136
Over 12			1	11	12	1	3	6	64	74

In group 3 there were 10 with pleural effusion, one of these men having a positive family history, and 28 with parenchymatous lesions, 2 having a family history of tuberculosis, 16 a suggestive previous history and 4 giving a history of previous sanatorium treatment

In group 4 there were 16 cases of pleural effusion, one with a family history of tuberculosis, and 136 with parenchymatous disease, one with a family history of tuberculosis and three with a suggestive previous history

In group 5 there were 12 cases of pleural effusion, only one of whom had any significant factor (a history of dry pleurisy some years before, and this was on the opposite side), and 74 with parenchymatous lesions, of whom difficulties of suture. Fortunately when stitches are inserted the sheaths often come back, moving over the bundles like a sleeve, but nothing of the kind happens when plasma is used, with the result that the bundles may be held together in the most irregular fashion. This state of affairs might, perhaps, be remedied by further resection of the bundles, but it is in just such cases that the greatest economy in resection often has to be observed.

This recital of difficulties might lead the reader to suppose that plasma is completely useless in secondary suture, but nevertheless there are many cases in which disparity in size, loss of substance, and retraction of the sheaths are not serious hindrances to the use of plasma. However, it must be emphasised that even if the surgeon knows that he is going to perform resection and suture of a nerve he can never be certain until the operation is well advanced that the case will be suitable for fibrin suture. If the following conditions are present then fibrin suture may be performed.

(*a*) Little or no tension at the suture line; moderate tension may be overcome by anchoring the stumps to the bed of the nerve by lateral sutures as shown in fig II.

(*b*) No great disparity in size of the resected surfaces. Moderate degrees of disparity in size (and of tension, too) may be remedied by the approximation of the nerve sheaths by two, three or four sutures (fig III). If after the insertion of a few sutures it is evident that there is little tendency for the proximal bundles to escape at the suture line plasma may well be employed to complete the operation.

(*c*) The nerve ends should lie in a situation where plasma can collect and form a small pond, since at the time of application the protein solution is fluid. The formation of a suitable pool is often assisted by tilting the operating table; by hooking up muscles or the margins of the wound with the small skin hooks used by plastic surgeons; and, lastly, little troughs may be made of bone wax like the clay troughs used by plumbers when pouring molten lead into a socket.

(*d*) A good reason for employing plasma is inaccessibility of the stumps. This is well illustrated by the case shown in fig II, where there was a division confined to the deep branch of the ulnar nerve. Suture by stitching could have been performed but the difficulties were great and it was much easier to anchor the stumps by single sutures at points slightly remote from the suture line, lay the cut surfaces in contact, and seal them together with plasma.

Grafts.—The mechanical conditions obtaining in nerve grafting (so far we have not used any grafts of large diameter) closely resemble those of animal experimental work and it is, therefore, not surprising to find that this is where fibrin suture is seen at its best. Fresh nerve grafts are notoriously difficult to handle (they are soft and slippery) and still more difficult to suture. On one occasion no plasma was available and we were compelled to use stitches instead, which made one appreciate all the more the great ease with which grafts may be held securely in position when plasma is used. There is no difficulty about tension, for the grafts should, if anything, be cut too long since it is known that they tend to shrink and shorten during the first weeks after operation. It is not usually difficult to lay them in good position, and if a sufficient number of grafts is available they make good contact with the whole of the cut surfaces of both central and peripheral stumps. It would, nevertheless, be an advantage to stick the grafts together with plasma before placing them between the stumps, and at the next opportunity we propose to lay the grafts in a small wax or metal trough of about the same dimensions as the gap to be repaired; pouring in plasma, and after it has coagulated removing the grafts "in aspic", and trimming the ends so that a smooth cut surface of bundles is presented to both central and peripheral stumps. If this is feasible then the final step is simple—a small quantity of plasma at each end will complete the sutures. Fig IV shows how anatomically perfect may be the repair in a case where an extensive lesion of C5 and C6 was replaced by cable grafts taken from the superficial radial nerve. One has no hesitation in saying that the introduction of fibrin suture has removed the greatest technical difficulty in nerve grafting, though it still remains to be seen whether repair by grafting of large defects in the major nerves is a worth-while procedure. At any rate this new technique has removed one of the major operative difficulties.

BEHAVIOUR OF THE FIBRIN COAGULUM IN MAN

As in so many other procedures connected with the repair of peripheral nerves, direct observation of the results of suture is rarely possible. However, in one case where a nerve graft was removed many months after its insertion (Seddon, Young and Holmes 1942) there was perfect union of both ends of the graft. But there the evidence ends. And when we have final records of the results in all cases in which fibrin suture has been employed it will still be impossible, unless (which is most unlikely) there are the most startling differences from the results of stitch-suture, to connect the final result with the nature of the suture material used. There is ample evidence that the perineural stitches of linen or silk offer little or no bar to regeneration; and even when stitches were passed through nerves Young and Medawar found that the fastest-growing pain fibres penetrated the peripheral stump as rapidly after stitching as after fibrin suture, though they were held up slightly longer in the suture-point scar itself. The merits of fibrin suture therefore lie essentially in the field of surgical technique and especially in the technique of nerve grafting.

The figures in the table, taken from the records of the peripheral nerve-injury centre at the Wingfield-Morris Orthopædic Hospital, Oxford, give some indication of the usefulness of fibrin suture.

SUMMARY OF OPERATION CASES

Nerve suture	Fibrin suture	Thread (silk or hair)	Fibrin and thread	Total
(*a*) Immediate repair	1	3		4
(*b*) Late repair	1	60	7	68
Grafts	6	1*		7
—	8	64	7	79

* No plasma available

SUPPLY

Although attempts to produce concentrated plasma on a commercial scale (in the form of a dried fibrinogen to be re-dissolved in human serum) have not yet been successful, there is no reason why local supplies should not be provided by a biochemical or pathological laboratory.

Experience accumulated during the course of preparing many samples of plasma showed that the description given by Young and Medawar (1940) may be modified in the following way. It is not necessary to wash the fibrinogen precipitate with distilled water provided that the supernatant fluid has been removed as completely as possible; but it is desirable to allow the fibrinogen precipitate to flocculate for twenty minutes instead of five.

Concentrated plasma keeps for about a week without deterioration, provided that it is stored in wax vessels, and the original plasma is known to be stable.

SUMMARY

A review is presented of the first series of peripheral nerve injuries in which fibrin suture has been given a trial at operation.

It is probable that plasma will prove of great value in primary suture of divided nerves.

It is unlikely that plasma will come into general use for secondary repair since the conditions that favour its use are present in only a minority of cases.

In the repair of large defects by grafting plasma is of great value and should be used in preference to all other suture materials.

MAJOR PROWSE PULMONARY HYPERÆMIA AND ŒDEMA

II

one had a positive family history, six had a suggestive previous history and three had previously undergone treatment in a sanatorium These findings are correlated in table III

Thus, of the 48 men with some significant factor in their personal or family history, 34, or 70%, broke down and had to be invalided from the Service within 6 months of enlistment *Alternatively, of the total of 62 men who* developed tuberculosis within 6 months of enlistment, 34, or more than 54%, had some suggestive factor in their previous history

AGE OF LESION

In every case an X-ray film of the chest was taken before the diagnosis was made, and each film was carefully scrutinised by at least two different members of the staff of the sanatorium with a view to determining if possible the duration of the lesion, and to answering the question whether radiological examination of these men at the time of enlistment would have revealed the presence of pulmonary disease The criteria adopted have been similar to those enumerated by Aspin and Stalker (1941)—duration of symptoms, extent and density of the lesions, evidence of traction and fibrosis, presence of cavitation and the clinical course of the disease The estimation of the radiological appearances of a lesion some time before the skiagram is actually taken is admittedly difficult, and in some cases in the present survey no accurate estimation could be made However, after all relevant factors had been taken into careful consideration, it was thought that in 201 cases—i e, 67% of this series—the lesion could have been detected by radiology at the time of enlistment The following case-histories, together with reproductions of the X-ray films, are typical examples of the cases in this group

CASE-HISTORIES

CASE 1 —Age 24, 8 months' service Rather subject to recurrent colds each winter, otherwise nothing relevant in personal history Mother alive but father died 5 years previously of "influenza and pneumonia" having had persistent cough and "bronchitis" for many years Patient developed a cough with greenish sputum within 3 weeks of enlistment Five months later had laryngitis and then developed difficulty in swallowing, but had no special treatment or investigation despite increasing lassitude and gradual loss of weight Ultimately had two fairly large hæmoptyses in quick succession and this focused belated attention on his chest On examination was found to have signs of extensive bilateral disease, with involvement of the larynx The sputum was heavily positive and X ray (fig I) showed extensive mottling over the whole of the right lung with cavitation throughout, and an area of heavy mottling over the mid zone of the left lung associated with calcified deposits at the hilum

CASE 2 —Aged 35, 6 months' service Father, one brother and 2 sisters had died within the preceding 4 years of phthisis, and the patient had had an attack of pleurisy on the right side 5 years ago Since then he had felt occasional pain and tightness in chest with slight cough each autumn and winter Shortly after entering Army cough had increased and become productive, and had noticed increasing shortness of breath for which he ultimately sought medical advice Sent here for investigation, and extensive clinical signs were found over right side of chest, and sputum was positive X ray (fig II) showed considerable fibrotic disease on right with well marked evidence of traction, shown by displacement and angulation of trachea and mediastinum, diminution in size of affected hemithorax, cramped intercostal spaces, increased obliquity of the ribs, flattening of diaphragm with adhesions over outer third, cicatrisation of upper zone of right lung, and infiltration over upper half of left lung

CASE 3 —Age 33, 7 months' service No family or personal history of tubercle Three months after enlistment felt below par and was easily tired, about a month later developed cough and sputum but did not report sick for another 3 months by which time had lost more than 2 stone in weight In examination, was very thin and wasted, and had obvious clinical signs of extensive bilateral disease Sputum heavily positive and X ray (fig III) showed very extensive fibro caseous disease on left side with cavitation at apex and large cavity in axillary region showing a well marked fluid level On right side extensive mottling with widespread confluent areas suggestive of a tuberculous bronchopneumonia, this element of the lesion clearly being of relatively recent origin

CASE 4 —Age 22 No family or personal history of tubercle, and says he was always well before enlistment Eighteen days after joining his unit had slight staining of sputum and a few days later complained of pain over left side of chest A week later was referred to hospital owing to persistence of symptoms, and X ray (fig IV) revealed well marked cavitation in right upper lobe with considerable pleural thickening over this zone, and diffuse infiltration over upper half of left lung which appears to be of recent origin with breaking down of lung tissue Had no sputum but a specimen of fæces was positive

CASE 5 —Age 30, 4 months' service No family or personal history of tubercle Lassitude, shortness of breath and laryngitis of two weeks' duration Sputum only scanty but positive on concentration, and X ray (fig V) showed extensive disease throughout left lung with considerable fibrosis especially over upper lobe, and several cavities in all zones (one below clavicle showing a fluid level), scattered mottling throughout right lung with thin walled cavity in mid zone

CASE 6 —Age 20, 3 weeks' service One brother developed tuberculosis during the preceding year and was at home for some months, occupying the same bedroom though he had a separate bed, before being admitted to a sanatorium Patient developed slight cough few weeks before examination by recruiting board, but neither X-ray examination nor further opinion was sought by the board After enlistment cough increased, sputum became purulent, and voice husky, five weeks later had small hæmoptysis and was sent to hospital Sputum heavily positive, and X ray (fig VI) revealed extensive disease of both lungs with large cavity in left upper lobe and definite fibrosis

COMMENT

Anxiety has been felt for some time by many workers in tuberculosis concerning the large number of men discharged from the Services with tuberculosis after having been passed as fit by the recruiting boards The above figures show that in this series more than two thirds of the servicemen who broke down with tuberculosis almost certainly had demonstrable disease before enlistment, and that the methods of examination at present used by the boards are inadequate as a means of detecting the symptomless case

The methods at present used are (1) ordinary clinical examination, (2) referring "suspicious" cases to hospital or the tuberculosis officer, (3) notification of known cases of tuberculosis to the board by the local tuberculosis officers, and (4) obtaining a statement from each man that he has not previously suffered from tuberculosis The first method is often hurried and cannot be regarded as a reliable means of detection except in cases with gross physical signs, while the last two methods

---

Legends to Illustrations on Plate

PROFESSOR SEDDON, MR MEDAWAR

FIG II —Division of the motor branch of the ulnar nerve secondary suture After excision of the damaged part of the nerve the wrist was flexed, and the stumps anchored by lateral sutures placed about 1 cm away from the cut surface Good approximation was obtained and the union completed with plasma

FIG III —Complete division of the main sciatic trunk secondary suture There was little disparity in size between central and peripheral stumps and the case was an ideal one for fibrin suture after rough approximation of the sheaths with fine silk stitches The watch maker's forceps were used to pull the sheaths together before the plasma was poured on

FIG IV —Untouched photograph taken at operation There was a complete lesion of the outer two thirds of the upper trunk of the brachial plexus, but the consistency of the inner third was so nearly normal that it was spared, and it did in fact contain one or two apparently healthy bundles The excised part of the trunk was replaced by three auto grafts from the superficial radial nerve The upper junction of the grafts cannot be seen

MAJOR BARRINGTON PROWSE

FIG I —One hour after accident, showing homogeneous opacity of both upper lobes with enhanced translucency of lower zones (*Inadvertently reversed in reproduction*)

FIG II —Twenty four hours after accident Apical opacity much reduced, no evidence of emphysema in lower zones

can only affect a small minority of recruits. Concerning the second method, Gregory Kayne (1940), describing his experience of 134 cases referred to him as a tuberculosis officer by the boards, gives the reason for reference of each case and found that a history of "pleurisy" in the past and a family history of tuberculosis headed the list. Other important reasons were previous stay in a sanatorium or attendance at a tuberculosis clinic many years before. Despite this, only 2 cases of active phthisis and 1 case of a "quiescent" early lesion were found (though there were 8 other men with healed phthisis), and Kayne concluded that these criteria could not be relied on to detect more than a small fraction of recruits with either active or healed pulmonary lesions.

Graham and Davies (1941) found that 5·7% of 1869 men referred to them in Wales by medical boards were suffering from pulmonary tuberculosis. Here, the main criteria for reference were history of contact, a significant past or present history, and the presence of abnormal physical signs. But the number of cases missed by relying only on these methods cannot be accurately known, and Kayne (1941) estimated that in the Welsh series only 13% of the men who might reasonably be expected to have unsuspected pulmonary tuberculosis at the time of their initial examination were in fact diagnosed.

Legends to Illustrations on Plate

DR CRAWFORD

FIG I (Case 1).—Extensive mottling with cavitation throughout right lung, heavy mottling in mid-zone of left lung with calcified deposits at hilum, 8 months' service, had symptoms for practically the whole period.

FIG II (Case 2).—Extensive fibrotic disease in right lung, infiltration of upper half of left lung, 6 months' service, bad family history.

FIG III (Case 3).—Extensive disease of both lungs with widespread consolidation on right side and multiple cavities on left side, 7 months' service.

FIG IV (Case 4).—Cavitation in the right upper zone with fibrotic disease, diffuse infiltration upper half of left lung, less than one month's service.

FIG V (Case 5).—Scattered mottling throughout right lung with thin-walled cavity in mid zone, extensive disease and considerable fibrosis in left lung with several cavities, 4 months' service.

FIG VI (Case 6).—Very extensive disease throughout both lungs with large cavity in left upper lobe, only 3 weeks' service, bad family history, had definite symptoms before enlistment.

DRS KEMP, MURRAY, WILSON

FIG I.—Lateral radiogram of a boy of 15 (case 4) showing irregular ossification of the epiphyseal nuclei and the end plates of the lower dorsal vertebræ (D7 and D11). Slight wedge formation of the vertebræ, slight dorsal kyphosis. (Bampton, Oxfordshire.)

FIG II.—Normal spine in a girl of 18 (nursing candidate) showing regular ossification of the end plates of the vertebral bodies. Small epiphyseal nuclei still remaining near the anterior angles.

FIG III.—Dorsal spine in a woman of 21 (nursing candidate). Dorsal kyphosis, wedge formation of the body of D8. Wavy outlines of the anterior ends of the bodies of D7 and D9. Osteophytic outgrowths from D7, D8 and D9.

FIG IV.—Lateral radiogram of the lower dorsal vertebræ and lumbar spine in a boy of 14 (case 14). Very deep nuclear expansions into the bodies of the vertebræ indicated by bowing of the end plates. Irregular ossification of the contour and edges of the end plates of the lower dorsal vertebræ and of the epiphyseal nuclei. Forward projection of the upper anterior angle of the body of L2. (Launton, Oxfordshire.)

FIG V.—Lateral radiogram of a boy of 13$\frac{11}{12}$ (case 23). Very deep nuclear expansions into the bodies of the lower dorsal vertebræ. Relatively normal lumbar vertebræ. Irregular ossification of the epiphyseal nuclei of the anterior ends of the end plates of the lower dorsal vertebræ with slight wedge formation. (Maldon, Essex.)

FIG VI.—Lateral radiogram of a boy of 14 (case 18). Shallow nuclear expansions in the bodies of the lower lumbar vertebræ. Regular ossification of the end plates, epiphyseal nuclei not visible. (Oxford city.)

Nevertheless, though the reasons for reference as given above may be inadequate to detect more than a small number of cases of phthisis, their importance should not be overlooked; and since in the present series one of the most significant facts revealed is that not one recruit had been X rayed, and only 4 had been referred to a tuberculosis officer, it appears that many boards are still not referring a sufficient number of doubtful cases for a second opinion and full investigation.

Most tuberculosis workers hold the view that all recruits should be subjected to a radiological examination as the only sure way of preventing the entry of tuberculous individuals into the Services. Heaf and Rusby (1940) have summarised the advantages of mass radiography in the examination of recruits, as follows. First, from every 2 million men recruited approximately 20,000 tuberculous or potentially tuberculous subjects could be excluded, the saving to the state in the cost of treatment and pensions can be readily appreciated if not accurately estimated. Secondly, documentary evidence of fitness or freedom from tuberculosis at the time of enlistment would be obtained. Thirdly, early examples of non-tuberculous pulmonary disease would be recognised at a stage when treatment could offer a greater chance of radical cure.

Galbraith (1941), on the basis of routine X-ray examination of more than 100,000 recruits in the Australian Army by miniature radiography, found that 1·04% showed evidence of tuberculous lesions not of the primary type, and in 0·56% the condition was active. All these recruits had passed the clinical medical examination. Similar surveys have been made in many countries, and the volume of evidence which has now accumulated shows that in unselected samples of the apparently healthy adolescent and young adult population the incidence of definite pulmonary tuberculosis of the adult type is between 0·5% and 1%. Seeing that nearly every case with such pulmonary lesions will give an abnormal X-ray picture it is clear that radiology is the only practical method of detecting these symptomless cases. In 1940, the Horder Committee considered the question of mass radiography in the examination of recruits, and while agreeing that miniature radiography was the ideal to be aimed at they felt that serious practical difficulties were involved, and the adoption of this method was therefore not recommended.

Lately the Horder Committee has reported again (Cmd 6353),[1] and states that the use of mass radiography is being developed by the Services for the examination of personnel as apparatus becomes available. While commending this step the committee still feels that the adoption of mass miniature radiography as part of the examination by medical boards is impracticable, and states further that the magnitude of the problem, contrary to its estimate in the mind of a section of the public, is very small. This conclusion is apparently based on the fact that a selected group of men revealed a very low incidence of pulmonary tuberculosis. But the findings recorded in this paper, taken in conjunction with the conclusions arrived at by other investigations, show that the problem cannot be minimised in any way, and will have to be considered energetically if tuberculous individuals are to be prevented from entering the Services.

CONCLUSIONS

An investigation of 300 consecutive cases of pulmonary tuberculosis admitted from the Services emphasises the need for more detailed examination of men prior to enlistment.

Two-thirds of the cases which were ultimately diagnosed as tuberculous could, in our opinion, have been detected at the initial medical examination had radiological methods been included as a routine procedure.

Only 48, or 16%, of the cases had a suggestive personal or family history, and, though the criteria for further investigation usually adopted by medical boards are important, they are in themselves unreliable as a means of detection of all but a small proportion of the total number suffering from pulmonary tuberculosis.

Though no attempt has been made to go into the financial implications of the problem as revealed by this

(Illustrations on Plate)

The radiological investigations to be described originated in the observation of the frequency of ‘ round back ” among children and adults in areas where mottled enamel was prevalent

The significance of fluorine as a trace element in human nutrition has received little attention except from those interested in tooth formation and dental caries Until recently it was considered that the lower limit at which fluorine in drinking water would give rise to mottled enamel was 1 part per million, but Sognnaes (1941) and Sognnaes and Armstrong (1941) have suggested that in Tristan da Cunha, where the fluorine in water is 0 2 p p m , there exists a ‘condition of “ threshold mottling,” evidenced by the white spots of a very mild degree of dental fluorosis It is concentrations of fluorine between these mentioned levels that are of interest in the observations to be described

As far as we can ascertain neither in America (Hodges et al 1941) nor in this country have skeletal changes been reported as associated with mottled enamel in human beings The bone changes of chronic industrial fluorine poisoning in man were observed for the first time by Flemming Møller and Gudjonsson (1936) in cryolite workers Cryolite—a double fluoride of sodium and aluminium containing as much as 54% of fluorine—is mined in Greenland and later refined for use in the manufacture of aluminium near Copenhagen Roholm (1937) reported on these workers and showed fluorine was the toxic factor responsible for the bone changes Clinically many of the workers were in poor health, and some showed signs of silicosis , the commonest complaints were various dyspeptic phenomena, shortness of breath and rheumatic attacks In rather more than half the workers there was restricted mobility of the spine and in severe cases almost complete rigidity Radiography shows a progressive osteosclerosis of all the bones, especially of the vertebræ, the pelvis and the ribs Changes may be detected after about two years' exposure At first the osseous pattern seems whiter and more blurred than normal , later both the cortical bone and the cancellous trabeculations become thicker until ultimately the osseous pattern may seem to be completely effaced and the bones appear marble white and structureless The bony contours are almost everywhere irregular and the attachments of the muscles become thickened and ossified so that the bones seem covered with excrescences There is considerable ligamentous ossification, especially about the intervertebral and costovertebral articulations In the limbs there may be ossification of all the principal tendinous insertions and of the interosseous membranes

In England, Wilkie (1940) has reported 2 cases of chronic industrial fluorosis in men working in a Sheffield factory producing aluminium fluoride and hydrofluoric acid The bone changes were identical with those described by Flemming Møller and his colleagues According to Hunter (1939) no changes have been reported in workers dealing with fluorspar, enamel glazing or glass

Findings in Adults

The present investigation was undertaken to determine whether any changes could be detected radiologically in the bones of persons with dental fluorosis in Oxfordshire Mottled enamel is quite common among the villagers, but relatively rare in Oxford city where cases are mostly confined to suburbs which used to derive their water-supply from local wells The first persons radiographed were adults from the village of Bampton They had been resident in the village since childhood and derived their water-supply from surface wells, with fluorine contents varying from 0 3 to 0 9 p p m The findings are summarised in table I

Case 1 —Man, aged 53 Edentulous, but son had severe dental fluorosis Complained of rheumatism Considerable dorsal kyphosis with restricted spinal movements, posture resembling picture of cryolite workers in Roholm's book Rounded dorsal kyphosis due to wedge formation of lower dorsal vertebral bodies (D7–D11) , calcified envelopes of Schmorl's nodes visible , marginal lipping of affected vertebræ and narrowing of disc spaces Slight lumbar lordosis , no other abnormality Pelvis normal

Case 2 —Man, aged 18, son of previous patient No complaints Severe dental fluorosis with pitting of enamel No obvious skeletal deformity Slight wedge formation of body of D8 and irregularities of end plates of many other vertebræ, both dorsal and lumbar Pelvis normal

Case 3 —Woman, aged 38, no complaints Edentulous, but son who used same water had moderate dental fluorosis No spinal deformity, and movements seemed normal Regular ossification of end plates , marginal lipping of all dorsal vertebræ, especially lower , anterior ends of disc spaces narrowed

The radiological appearances of these cases were attributed to degenerative lesions of the intervertebral discs, and since there was no evidence of osteosclerosis they were dismissed as negative for signs of chronic fluorine intoxication. In view of these findings, which were supported by the experience gained in routine radiological examinations in the departments of the Radcliffe Infirmary and the Wingfield-Morris Orthopædic Hospital, where many patients are radiographed for spinal deformities and chronic rheumatism every year, it was thought that no further investigations among adults were worth while, for if the typical skeletal changes of chronic fluorine intoxication occur in Oxfordshire they must be very uncommon It must be admitted that the fluorine intake of the three cases under investigation was not high

Findings in Children

We decided to examine a group of children to see whether any disturbances of natural growth could be determined, since we argued that a minimal toxic factor would be most liable to produce changes during the most active phases of bone growth, and in those situations most subject to stresses and strains The spine was selected for examination because, towards puberty, growth is centred in relatively thin layers of tissue in the end plates of the bodies of the vertebræ which are subjected to considerable changes of pressure with every movement The children were rated clinically and examined for deficiency disease as described elsewhere (Wilson 1941b)

BAMPTON, OXFORDSHIRE

The first group includes 4 children of a Bampton family The father is an agricultural labourer and for many years contributed little money to maintain his family Judged from his economic standard his elder children were ill-nourished for many years In the last 3 years the economic conditions of the family have bettered and there has been a corresponding improvement in general health The family derived their water from a surface well containing at different times 0 3–1 2 p p m of fluorine All the children show severe dental fluorosis with pitting of the teeth

Case 4 —Boy, aged 15 Severe dental fluorosis Stocky build Head carried forwards Slight dorsal kyphosis and lumbar lordosis Anterior bowing of cervical spine but no structural malformations , upper 6 dorsal vertebræ relatively normal, showing regular ossification of end plates and epiphyseal nuclei , lower dorsal vertebræ showed flattening of bodies and slight wedge formation of D7 and D8 , irregular ossification of end plates and epiphyseal nuclei (fig I) Anterior third of bodies showed very irregular ossification, anterior epiphyseal nuclei being larger than normal, irregularly sclerosed and fragmented, and compressed into vertebral bodies which themselves showed irregular reactionary sclerosis L1 showed similar changes, L2 and L3 less definite changes , L4 and L5 relatively normal Intervertebral disc spaces narrowed in lower dorsal region , small nuclear expansions analysis, it is clear that the admission of such men to the Services is wasteful and uneconomic, and the cost to the country is out of all proportion to the value of these men as members of the fighting services They have to be equipped and trained and cost the country a considerable sum of money for short and unsatisfactory periods of service They constitute a danger to other troops who are necessarily thrown in close proximity to them under camp or barrack conditions Valuable hospital time and accommodation is taken up by these men before the diagnosis is established and their discharge arranged Further, there is the financial burden to the state represented by the cost of pensions for a number and the treatment for all

Finally, since radiological investigation is the only reliable procedure for the detection of clinically unsuspected cases of pulmonary tuberculosis, it is hoped that the Horder Committee will now reconsider the problem in the light of these and other recent findings Manufacturers of apparatus would, we believe, willingly cooperate with teams of tuberculosis physicians and radiologists in any endeavour to set up centres for the detection of tuberculous cases by the use of mass methods and we are convinced that the results would amply repay the expenditure involved

I am indebted to Dr J B McDougall, medical director, for permission to carry out this analysis and for his guidance and criticisms

ACUTE PULMONARY HYPERÆMIA AND ŒDEMA OF UPPER LOBES

C Barrington Prowse, M B CAMB , M R C P
TEMPORARY MAJOR, R A M C

(*Illustrations on Plate*)

The following case presented an unusual clinical picture and demonstrates the important part played by mechanical factors, particularly gravity, in the production of hyperæmia of the lungs

A leading aircraftsman crashed in an aeroplane when landing The plane buried its nose in the ground and he was pinned in the cockpit upside down, standing on his head and bent forwards over a gun, which drove into his chest causing a depressed fracture of the manubrium He also sustained a crush fracture of the anterior part of the body of the fourth thoracic vertebra After the crash he remained in this position for about half an hour before he could be released

When seen about an hour after the accident, he was pale, slightly cyanosed, and had a fast pulse of poor tension He complained of pain in the upper part of his chest made worse by movement and any but the shallowest breathing His respiration rate was raised and breathing was interrupted from time to time by little short coughs, which produced pink stained frothy sputum The chest was held in the inspiratory position and some bulging of the chest wall was noticeable in its lower part There was a little subcutaneous swelling and bruising of the central part of the chest wall at the level of the manubrium , this extended to just beyond the sternoclavicular joints on each side and up into the root of the neck around the lower end of the left sternomastoid muscle There was no surgical emphysema The head was poked forward and a sharp hump was noticeable in the upper part of the back , the second and third thoracic spines formed the most prominent part of this and the fourth was tender on pressure Movement of the chest was restricted, more so at the apices, particularly the right Vocal fremitus was reduced, though everywhere present , but, whereas the percussion note was hyper resonant at the bases and in the axillæ, at the apices it was relatively impaired, down to the level of the third space on the left and the fourth on the right The breath sounds were faint at the apices and obscured by bubbling râles and crepitations , elsewhere they were without accompaniments, and loud and harsh in spite of the limited respiratory excursion The area of cardiac dullness was diminished , the apex beat was not palpable, but the heart sounds were best heard in the fifth space just to the left of the sternum , they were normal and there were no added sounds

The physical signs suggested acute œdema of the upper lobes, more severe on the right side, with compensatory emphysema at the bases, more pronounced on the left and causing displacement of the heart to the right This was confirmed by X ray examination (fig i), which showed homogeneous opacity of both upper zones, extending slightly lower on the right side, and a high degree of translucency in the lower zones There was no sharp line of demarcation between opaque and translucent areas, but a gradual merging of the one into the other

The man had been somewhat shocked on admission, but rest, warmth and morphia improved his general condition He was placed on his back with the shoulders slightly raised , in this position, although there was still pain with breathing, the acute respiratory distress was soon much relieved In view of the possible danger of pulmonary infection, particularly since he said he had had a cold for the past twenty four hours, he was immediately put on full doses of sulphapyridine as a prophylactic measure

Next day, although pain in the upper part of the chest was severe, he had no respiratory distress Breath sounds were now quite good at the apices and a few medium rales were the only accompaniments All evidence of compensatory emphysema had disappeared X ray (fig ii) showed considerable clearing of the apical opacity, no evidence of emphysema in the lower zones and the heart shadow restored to its normal position

Subsequent progress of the pulmonary condition was uneventful save for the development, ten days after admission, of physical signs of partial collapse at both bases This was not accompanied by any untoward symptoms, and although the pulse rate remained between 80 and 90 per min his temperature and respirations were normal after the fourth day It did however delay treatment of the spinal deformity, but four weeks after the accident this was reduced under an anæsthetic and a plaster of paris jacket was applied A radiogram taken three weeks after the accident showed no abnormality in the lungs

DISCUSSION

Hyperæmia of the lungs is usually described as being either active or passive, according as it arises from an *increased supply of blood to the lungs or* is the result of an impeded venous return from them In the present case both factors were probably at work, which would account for the very acute onset of symptoms , obstruction to the venous return, however, was almost certainly the more important of the two

Active hyperæmia is associated with an active and healthy heart action, whereas passive hyperæmia is usually encountered with a diseased and weakened heart In the present case the heart muscle was good and the lungs were therefore richly supplied with blood, probably at an increased pressure, because of the inverted position, but the venous return was impeded, partly from the same cause and partly as a result of pressure at the site of injury, exerted principally on the relatively thin walled pulmonary veins at their entry into the left atrium Mechanical factors therefore were the most important on this occasion and gravity not the least of these, which should provide an effective reply to the sceptics who would have us believe that this force plays *no part in the production* of basal pulmonary " congestion "

When first seen, this patient presented many of the clinical features which have been described in connexion with blast injury to the lungs—notably shock, dyspnœa, cyanosis, pain in the chest, hæmoptysis, chest held in the inspiratory position, bulging of the chest wall, poor respiratory excursion and weak breath sounds with crepitations and bubbling rales If a victim of a bomb explosion received the injuries detailed in this case and was thrown into a similar position of inversion either condition might be present, and it would be important to be able to decide whether he was suffering from blast injury to his lungs or from the less serious condition here described Features suggesting blast injury would be the disproportionate degree of shock by comparison with the external evidence of injury, the greater restlessness, the even distribution throughout both lung fields of physical signs found only in the upper zones in this case, and the absence of compensatory emphysema

OXFORD CITY

Four Oxford city children were examined They were relatively poor but their general nutrition was considerably better than that of the poor Bampton and Launton children They had no signs of dental fluorosis and their drinking water contained no fluorine

CASE 18 —Boy, aged 14 Poor posture Irregular ossification of end plates with small Schmorl's nodes in dorsal region and slight nuclear expansions in lumbar region (fig VI), no wedge shaped deformities, no epiphyseal nuclei visible

CASE 19 —Boy, aged 13 Fair posture Regular ossification of end plates except for tiny irregularities suggesting small Schmorl's nodes, epiphyseal nuclei visible as thin regular plates, no wedge shaped deformities

CASE 20 —Boy, aged 13 Tall, fair posture Radiography showed no deformities, ossification regular, epiphyseal nuclei visible as thin regular plates

CASE 21 —Boy, aged 13 Tall, slight build, fair posture Radiography showed regular ossification and no deformities, epiphyseal nuclei not visible

In two of these children (cases 18 and 19) there were slight changes similar to those described in three of the Launton children (cases 15, 16 and 17)

The findings in these small groups of cases showed that disturbances in the natural ossification of the vertebral bodies are fairly common among children There was no definite evidence that fluorine was responsible, but, since in two cases (cases 4 and 5) severe changes were associated with severe dental fluorosis, it was thought possible that fluorine might have influenced the abnormal bone development This suggestion seemed to be supported when a number of other cases showing similar structural changes in the spine were found to be associated with dental fluorosis Accordingly it was decided to make a further examination of a group of children from Maldon in Essex, where the fluorine content of the water-supply reaches 5 p p m (Bowes and Murray 1936)—a level considerably higher than that in Bampton or Launton

MALDON, ESSEX

This group comprises 6 children Their general nutrition was comparable with the Oxford city children; all had severe dental fluorosis

CASE 22 —Boy, aged $13\frac{11}{12}$ Slight dorsal kyphosis and lumbar lordosis Slight wedge shaped deformities of many dorsal vertebræ, end plates regular, deep nuclear expansions in lower dorsal and whole lumbar spine, epiphyseal nuclei not visible

CASE 23 —Boy, aged $13\frac{11}{12}$ ' Dorsal spine straight, lumbar lordosis No definite deformities of ossification in upper dorsal vertebræ D11 and D12 showed wedge shaped formation of anterior halves of bodies and irregular ossification of anterior limits of end plates, only the epiphyseal nuclei of these vertebræ were present, anteriorly they were fragmented and compressed into the vertebral bodies L1 and L2 showed milder changes D11, D12 and all lumbar vertebræ showed deep nuclear expansions (fig V)

CASE 24 —Boy, aged $13\frac{11}{12}$ Slight lordosis Very deep nuclear expansions in lower dorsal and all lumbar vertebræ, no other structural deformities, epiphyseal nuclei visible in dorsal region

CASE 25 —Boy, aged $13\frac{3}{12}$ Slight kyphosis and lordosis Slight irregularities of end plates of dorsal vertebræ, slight wedge formation of D8, lower dorsal and all the lumbar vertebræ showed deep nuclear expansions, no epiphyseal nuclei visible

CASE 26 —Boy, aged $13\frac{4}{12}$ No definite clinical deformity Appreciable wedge formation of many dorsal vertebræ and slight irregularities of ossification of end plates, many deep nuclear expansions in lower dorsal and lumbar regions but not all these vertebræ were affected, epiphyseal nuclei not seen

CASE 27 —Boy, aged $14\frac{1}{2}$ Lordosis, no dorsal curvature Slight wedge formation of many dorsal vertebræ, end plates fairly regular apart from one or two small Schmorl s nodes, epiphyseal nuclei visible in dorsal region, lumbar spine showed nuclear expansions but not so deep as in other cases

All 6 Maldon cases showed definite structural changes In case 23, two of the vertebræ showed changes similar to those of case 4, but in the others the changes were not so severe Many cases showed appreciable wedge-formation but clinically lordosis was much commoner than kyphosis Deep-nuclear expansions in the lumbar region were seen in 5, and were more definite than those observed in the Oxfordshire cases other than case 14

Subsequent Course of Spinal Changes

It will probably be difficult to follow up all these cases to see what happens in later life In 2 instances (the twins, cases 6 and 7) the changes seemed to show spontaneous improvement within 12 months, probably related to improved general nutrition or to change of postural habits In other instances similar structural deformities have been known to improve, but many persist Some idea of the frequency of these deformities may be gathered from the records of a number of young adults male and female All appeared healthy and none had symptoms referable to the spine The radiograms available for examination were lateral views of the chest showing part of the dorsal spine, and were taken in the course of a chest survey among medical students and nurses The findings are shown in table II

Discussion

Endemic dental fluorosis occurs in many parts of the world but cases of chronic fluorine intoxication with skeletal changes seem to be comparatively rare Shortt

NE = Not examined

into bodies of lower dorsal and lumbar vertebræ, shown by bowing and local sclerosis of end plates

CASE 5—Boy, aged 13, brother of previous case Severe dental fluorosis, nutrition subnormal Slight dorsal kyphosis and lordosis Radiographic appearances similar to case 4, but less well marked, most striking changes were in D12 and L1 Epiphyseal nuclei present but small Slight spondylolisthesis present with associated defect in neural arch of L5 A year later boy had left school and was earning satisfactory wages Nutrition good Forward projection of anterior angles of bodies of D12 and L1, with slight wedge formation, epiphyseal nuclei still small or absent Better calcification than in case 4

CASE 6—Girl, aged 11, sister of previous two cases Severe dental fluorosis, nutrition subnormal, no definite abnormalities Radiographic appearances similar to but less definite than in case 5 Changes greatest in lower dorsal and upper lumbar spine Epiphyseal nuclei of dorsal spine all present, relatively large and very dense in lower dorsal region Anterior angles of some of dorsal bodies compressed forwards, but no wedge shaped deformity A year later irregularities not so well marked, ossification of end plates improved, nuclear expansions visible in lower dorsal and lumbar regions Had grown slightly

CASE 7—Twin sister of preceding case Severe dental fluorosis, nutrition subnormal Definite dorsal kyphosis and lumbar lordosis Slight wedge formation of several dorsal vertebral bodies, other appearances similar to case 6 A year later only slight dorsal kyphosis present, dorsal spine straighter and deformity of vertebræ less, end plates regular, and only slight nuclear expansions, epiphyseal nuclei well formed but very dense

All 4 cases belonging to the same family showed radiological evidence of a disturbance of natural ossification involving dorsal and lumbar vertebræ, the lower dorsal and the upper lumbar bodies were most affected The changes were a disorganisation of ossification of the end plates of the affected vertebræ and the epiphyseal nuclei, with compression deformities of the vertebral bodies and narrowing of the intervertebral disc spaces The eldest child showed the most definite changes His brother, a year younger, was not so severely affected when examined originally, and at a second examination, a year later, the appearances were not much worse The twin girls showed fewer changes than the second brother, and a year later both showed definite improvement It is possible that their favourable progress was related to the improved financial circumstances of the family due to the inheritance of an uncle's savings

Two other families in Bampton were examined and similar appearances were shown

CASE 8—Girl, aged 15 Member of large poor family Severe dental fluorosis, nutrition subnormal Slight dorsal kyphosis, slight deformities of vertebral bodies, irregular ossification of end plates, small nuclear expansions in dorsal and lumbar regions, epiphyseal nuclei visible Appearances similar to cases 6 and 7

CASE 9—Girl, aged 11, sister of case 8 Severe dental fluorosis, nutrition subnormal No spinal deformity, irregular ossification of many end plates, well marked nuclear expansions in lumbar region, only few epiphyseal nuclei present

CASE 10—Girl, aged 9, younger sister in same family Severe dental fluorosis, nutrition subnormal, slight kyphosis Slight wedging of many vertebral bodies, slight irregularities of end plates, no definite nuclear expansions, epiphyseal nuclei not present

CASE 11—Girl, aged 10, only child Mild dental fluorosis, nutrition subnormal Slight kyphosis and slight wedge formation of several dorsal bodies, many upper dorsal bodies showed forward projection of anterior angles suggesting protrusion of intervertebral discs, irregularities of end plates, small nuclear expansions

The mother and maternal uncle of case 11 were examined

CASE 12—Mother of case 11, aged 37 Very mild dental fluorosis, occasional backache Slight dorsal kyphosis, restricted spinal movements, no wedge shaped vertebræ, regular end plates, no Schmorl's nodes, narrowing of anterior ends of many intervertebral discs of dorsal spine Forward protrusion of anterior angles of dorsal vertebræ, no true osteophytic lipping

CASE 13—Uncle of case 11, aged 38 Farm labourer Mild dental fluorosis, nutrition good Slight dorsal kyphosis, irregularity of end plates, few small Schmorl's nodes, slight osteophytic outgrowths Lumbar spine normal

LAUNTON, OXFORDSHIRE

The next group comprises 4 children from the village of Launton where severe dental fluorosis is common The water-supply contains 0 8 p p m of fluorine The children of two schools—one elementary, one secondary—were interviewed In the elementary school there were many ill-nourished children showing poor posture, 4 were selected for examination, 2 apparently well nourished and 2 ill nourished

CASE 14—Boy, aged 14, tall and well built Moderate dental fluorosis Social conditions of home unsatisfactory Slight dorsal kyphosis, slight wedge formation of some dorsal bodies Ossification deep to end plates of vertebræ shown as irregular dense bands, much wider than normal, forming upper and lower borders of vertebral shadows, epiphyseal nuclei large and very dense but not displaced, very deep nuclear expansions in dorsal and lumbar regions, indicated by bowing of end plates with considerable reactionary sclerosis of bone, forward projection of upper anterior angle of L2, narrowing of intervertebral disc spaces in dorsal region (fig IV)

This case showed considerable disorganisation of the natural ossification of the end plates but no changes in the anterior thirds of the bodies as in case 4

CASE 15—Boy, aged 10, stocky and well built Moderate dental fluorosis Social conditions of home very good Slight wedging of one dorsal vertebra, slight irregularities of end plates, small epiphyseal nuclei

CASE 16—Boy, aged 13, short, thin and ill nourished Severe dental fluorosis Home conditions poor No wedge formation, slight irregularities of end plates, epiphyseal nuclei not ossified

CASE 17—Boy, aged 11, short, thin and ill nourished Severe dental fluorosis, no wedge formation, slight irregularities of end plates, small Schmorl's nodes in dorsal region, epiphyseal nuclei not ossified

One of these children (case 14) showed severe changes in the spine but the other 3 showed only slight departures from the normal Case 14 was a tall boy whose radiographic appearances were consistent with recent growth The other boys were relatively short and the epiphyseal nuclei were small or absent

CHRONIC DIARRHŒA
DUE TO *TRICHOCEPHALUS TRICHIURUS*

DAVID F ROSS, M B ABERD
LATELY HOUSE PHYSICIAN AT ABERDEEN ROYAL INFIRMARY
(*Department of Medicine, University of Aberdeen*)

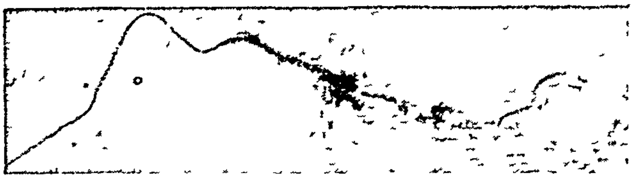
THE human whipworm has been reported in this country as an interesting but unimportant intestinal parasite (Still 1918, Manson-Bahr 1938) but the case reported here demonstrates that the worm may occasionally upset its host considerably

A rather pale, but otherwise healthy looking married woman aged 28 was admitted to hospital with an exacerbation of chronic diarrhœa which had troubled her intermittently for 5 years The original onset had been sudden, and for 5 months she passed five or six fluid stools a day At times during this period there was a little blood and mucus in the stools, but the symptoms were never severe enough to confine the patient to bed Thereafter the diarrhœa abated, but returned at each menstrual period This state of affairs continued until about 6 months before admission, when she began to be easily tired and a little breathless on effort These symptoms became steadily worse and 14 weeks before admission the diarrhœa again became continuous, and so severe that she was forced to go to bed This attack was accompanied by some colicky left-sided abdominal pain, and at times by tenesmus

On admission she was passing 4–6 semi liquid stools daily, and the pain and tenesmus continued The only abnormal finding was a palpable descending colon which was contracted and somewhat tender, especially in the left iliac fossa Her blood showed a hypochromic microcytic anæmia with a hæmoglobin level of 56%, red cells 3,540,000, white cells 7300 per c mm (eosinophils 13%) A fractional test meal showed complete achlorhydria, and her stool contained a few red cells and pus cells, and the distinctive barrel shaped ova of *Trichocephalus trichiurus* On these findings, apparent clinical trichocephaliasis was diagnosed Barium meal and enema examination had been made before admission, without showing any abnormality, to complete the investigation sigmoidoscopy was performed This confirmed the diagnosis in a remarkable manner, showing a little reddening and thickening of the mucosa of the lowest 9 in of the bowel, most conspicuous about 7 in from the anus where the mucous membrane was seen to be covered by a layer of sticky mucus, underlying which were several hæmorrhagic spots 1–2 mm in diameter, attached to some of these spots moving whipworms could be seen, and several were removed with forceps One specimen recovered in this way was found on microscopic examination to have a collar of bowel mucosa adhering to the junction of the thin anterior portion with the thick posterior portion (see figure)

Hexylresorcinol was chosen as the most suitable of the available anthelmintics (Lamson et al 1931), and after a short period of starvation and purgation 0 9 g of the drug was given by mouth This resulted in the excretion of an enormous number of dead worms in the succeeding few days, and the abdominal pain and tenesmus disappeared After a week, as the patient was still having about 4 bowel movements daily, the drug was given again with a similar result, this also failed to stop the diarrhœa, so after another week a further dose, this time of 1 6 g, was given On this occasion daily examination of blood films revealed that the eosinophilia, which was 13% on the day of treatment, rose to a peak of 21 5% two days later and declined thereafter No toxic manifestations occurred

The patient was discharged at this stage, and when seen two months later was completely free from diarrhœa and abdominal pain, but still complained of a little tiredness and breathlessness, although these were much less than before admission Her stool still contained a large number of ova, but the excretion of dead worms had ceased Specimens of fæces from her two daughters were examined, and both were found to be excreting ova in fairly large numbers, especially the younger, aged 18 months, who was quite heavily infested Neither had any symptoms referable to the condition



Male *T dispar* 2 8 cm long, the neck accounting for 2 1 cm of the length The body is in a spiral, and the terminal spicule, alimentary canal and testis can be distinguished Surrounding the junction of neck and body is a fragment of intestinal mucosa, in which the intestinal epithelial cells are recognisable when stained with toluidin blue (Report by Dr A H Cruickshank) ×7

DISCUSSION

Little information exists regarding the incidence of trichocephalus infestation in this country, which is not surprising considering how seldom it produces symptoms Still (1918) found the worm at autopsy in the cæcum of 8% of children, but he never saw more than three or four worms in a single case, and was never able to diagnose the condition during life He also records that there was invariably a coexisting infestation with threadworms Manson-Bahr (1938) has found the ova in the stools of children in Kent The incidence is probably much less now than it was at the time of Still's observations owing to improvements in sanitation in the past 20 years, in the north-east of Scotland it must be very low since, in Aberdeen, the ova have not been seen in the routine microscopic examination of stools, nor the worms observed in the intestine at autopsy, for the last 5 years

It was impossible to trace the original source of the infestation in the case described, but the circumstances which brought about the gross degree of infestation are interesting

The patient has been living in her present house in a small country town for the past 10 years, and until 3 years ago the disposal of excreta was effected by a pail closet which was emptied into a hole dug in the garden adjoining the house In the same part of the garden vegetables were grown, including a large number of lettuces The patient confessed to a great liking for lettuces, and was in the habit of eating some almost every day while they were in season, thus probably reinfesting herself regularly and heavily The children did not share her liking for lettuce and are less heavily infested The husband who ate no lettuce, is on active service and not available for examination

It is impossible to assess the number of worms harboured by the patient on admission, but it is estimated that over 1000 were removed during treatment Estimation of the number of worms present by means of egg counts on fæces is not of value, since the number of eggs per female worm varies inversely as the number of worms present (Miller 1939)

It is usually taught that whipworms themselves produce no symptoms, although they are commonly found along with other parasites, such as the threadworm, ascaris or the hookworm, which may produce symptoms Swartzwelder (1939), however, analysed 81 cases in which symptoms were considered to be attributable to a pure whipworm infestation He found that the commonest symptoms were abdominal pain, usually right-sided, and vomiting Constipation was commoner than diarrhœa which was noted in only 5 cases Most of the cases showed some anæmia, but a hæmoglobin of less than 70% was uncommon Eosinophilia of over 6% was present in 6 out of 34 cases In the case reported here, the absence of other ascertainable cause for the diarrhœa, its amelioration after

and his colleagues (1937) reported a study of 10 cases in the Madras Presidency where mottled enamel is common in some districts though the village children do not appear to suffer from the intake of fluorine. At about 30 years of age the first signs of intoxication appear, evidenced by a general tingling in the limbs and body generally. Pain and stiffness next appear, especially in the lumbar spine. The stiffness increases until the entire spine, including the cervical region, behaves like a continuous column of bone. There is stiffness of other joints and ossification of the periarticular tissues, tendinous insertions and interosseous fasciæ. The ribs become fixed and the breathing entirely abdominal. By the time the condition is fully developed the patient is about 40, there is much cachexia and death ensues from intercurrent disease. There are minor variations, and all cases in a village do not exhibit the same degree of intoxication. The amount of fluorine in the drinking water responsible for these cases was between 3 and 4 p.p.m. In 6 of Shortt's 10 cases the amount of fluorine in the urine was much above normal. The published radiograms of these Madras cases showed changes similar to those of the cryolite workers. Though the clinical appearances resemble ankylosing spondylitis the radiographic findings bear no resemblance to it, for in chronic fluorosis the articular cartilages of the joints are preserved.

Changes similar to those in Shortt's cases have been reported from South Africa by Ockerse (1941), who found 15 areas in the Pretoria district where mottled enamel is endemic. The fluorine content of the water in 10 of these varied from 1.43 p.p.m. to 13.9 p.p.m. Though he was able to report 8 cases among natives who drank water containing 11.98 p.p.m. of fluorine, his inquiries among doctors failed to reveal any other cases simulating chronic fluorosis. He suggests that there may well have been people with less obvious symptoms.

The development of the disease is influenced by several factors. Pundit and his colleagues (1940) found that bone changes in fluorosis bore a definite relationship to the economic and nutritional status of communities. In England, severe cases are unlikely to occur because social conditions are on the whole satisfactory. If fluorine causes any ill effects they are most likely to be found in childhood during the active phases of growth, when latent deficiencies or toxic factors are best revealed. Several workers have found that in mottled enamel good structure (i.e., absence of pitting) is associated with a good state of nutrition, and it has also been shown that the fluorine content of bones increases with age (Glock, et al. 1941), but so far no-one has investigated the effects of fluorine in the bones of growing children.

In this short series of cases we have found that disturbances in the natural ossification of the spines of children are very common. Though some of these defects probably heal or improve, we found many young adults with similar deformities and with early signs of spondylosis deformans (spondylitis osteo-arthritica). We notice that dental fluorosis is commonly associated with such changes but we have no evidence to prove that fluorine is solely responsible: changes of a similar nature, though less definite, were demonstrated in children showing no signs of dental fluorosis, and not all children with severe dental fluorosis had changes in the spine, whereas some with only slight mottling showed significant deformities.

These results are put forward as a preliminary investigation, since it will be necessary to study the growth of bone in groups of children of different ages over several years, taking into account nutrition, posture, rate of growth, habits and occupation. We believe that fluorine in the water-supply may influence the development of such defects especially when it is associated with defective nutrition.

The radiographic appearances of the cases here described are similar to those described by Scheurmann (1921) in cases of adolescent kyphosis, but none of our cases had symptoms. Scheurmann attributed the changes to disordered ossification of the epiphyseal centres of the vertebral end plates analogous to Perthes's disease of the femoral head; wedge-formation of the vertebræ resulted from compression of the bodies anteriorly, together with defective growth of the compressed bone. Later Schmorl (1929–30) suggested that the radiographic appearances could be attributed to herniations of the nucleus pulposus of the intervertebral discs into the bodies of the affected vertebræ, with the result that the vertebral bodies were subjected to increased strain anteriorly. The disorganisation of the epiphyseal nuclei and the wedged vertebræ were secondary to compression and defective growth of the compressed tissues. Radiographically, such hernias cannot always be discovered, because of the absence of reactive changes in the bone; for it is not the prolapse but the bony envelope around it which is visible in the film. Subsequently, Scheurmann (1936) recognised that changes may begin a few years before the appearance of the epiphyseal nuclei, but he did not modify his opinion that the condition was due to a disturbance of growth. He considered that the appearances were due primarily to irregularity of the formation of the "limbus vertebralis" with ultimate nuclear prolapse.

These different opinions have caused considerable controversy, and it is now generally agreed that, whereas Schmorl's view offers a satisfactory explanation in some instances, other cases are best described as a disturbance of growth associated with abnormal posture.

Children with adolescent kyphosis are not often seen in hospital practice, though the condition is far more common than is generally supposed. In typical cases there are characteristic deformities: the head is carried forward and the shoulders are rounded. There is a rigid rounded kyphosis of the dorsal region and a varying degree of lumbar lordosis. We have shown radiographically that similar malformations commonly occur in children and young adults without manifest deformities. These findings are in accord with clinical experience, for in Oxford, over 3 years, 74% of cases of dorsal kyphosis referred for radiographic examination were under 50 years of age. There was no clear distinction between adolescent and senile kyphosis. Many cases conforming to the description given by Beadle (1931) of senile kyphosis were seen in young adults of both sexes.

We believe that spondylosis deformans (spondylitis osteo-arthritica) may be the result of progressive degeneration, during life, in malformations acquired in youth. If this is so, such changes should be preventable if we can ensure the proper development of children.

In the schools of Oxfordshire it has been suggested that increased emphasis on posture during physical training would be useful early treatment of this spinal condition among children whose general nutrition is already benefiting from additional milk and school dinners.

SUMMARY

Though skeletal changes in association with dental fluorosis have been reported in India and South Africa no similar observations have been published in America or Britain.

A radiological investigation has been made of 27 people (5 adults and 22 children) to determine whether mottled enamel due to fluorine was associated with skeletal changes.

Findings suggest that disturbances of natural ossification are fairly common among children, but there was no definite evidence that fluorine was responsible, though in 2 cases severe skeletal changes were associated with severe dental fluorosis and 6 children from Maldon in Essex with severe mottled enamel all showed disturbance of ossification.

Signs of similar developmental disturbances and early spondylosis deformans were found among many young adults, in some of whom dental fluorosis was also noted.

These findings are in accord with clinical experience which suggests that spondylosis deformans is the result of the progressive degeneration of malformations laid down in youth. We conclude that fluorine in soil and water, in association with defective nutrition, may favour such maldevelopment.

We wish to thank the county medical officer of health for Essex and his staff for giving us opportunities to X ray Maldon children, and the Medical Research Council for a grant towards the expense of the investigation.

CHRONIC DIARRHŒA
DUE TO *TRICHOCEPHALUS TRICHIURUS*

DAVID F. ROSS, M.B. ABERD.
LATELY HOUSE PHYSICIAN AT ABERDEEN ROYAL INFIRMARY
(*Department of Medicine, University of Aberdeen*)

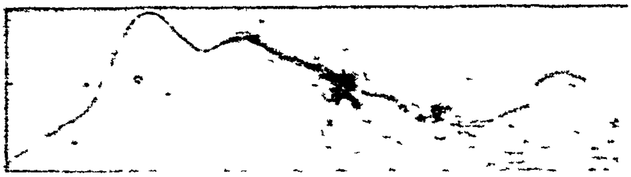
THE human whipworm has been reported in this country as an interesting but unimportant intestinal parasite (Still 1918, Manson-Bahr 1938) but the case reported here demonstrates that the worm may occasionally upset its host considerably.

A rather pale, but otherwise healthy looking married woman aged 28 was admitted to hospital with an exacerbation of chronic diarrhœa which had troubled her intermittently for 5 years. The original onset had been sudden, and for 5 months she passed five or six fluid stools a day. At times during this period there was a little blood and mucus in the stools, but the symptoms were never severe enough to confine the patient to bed. Thereafter the diarrhœa abated, but returned at each menstrual period. This state of affairs continued until about 6 months before admission, when she began to be easily tired and a little breathless on effort. These symptoms became steadily worse and 14 weeks before admission the diarrhœa again became continuous and so severe that she was forced to go to bed. This attack was accompanied by some colicky left-sided abdominal pain, and at times by tenesmus.

On admission she was passing 4–6 semi-liquid stools daily and the pain and tenesmus continued. The only abnormal finding was a palpable descending colon which was contracted and somewhat tender, especially in the left iliac fossa. Her blood showed a hypochromic microcytic anæmia with a hæmoglobin level of 55%; red cells 3,540,000; white cells 7[illegible] per c.mm. (eosinophils 13%). A fractional test-meal showed complete achlorhydria, and her stool contained a few red cells and pus cells, and the distinctive barrel-shaped ova of *Trichocephalus trichiurus*. On these findings, apparent clinical trichocephaliasis was diagnosed. Barium meal and enema examination had been made before admission, without showing any abnormality; to complete the investigation sigmoidoscopy was performed. This confirmed the diagnosis in a remarkable manner showing a little reddening and thickening of the mucosa of the lowest 9 in. of the bowel, most conspicuous about 7 in. from the anus where the mucous membrane was seen to be covered by a layer of sticky mucus, underlying which were several hæmorrhagic spots 1–2 mm. in diameter; attached to some of these spots moving whipworms could be seen and several were removed with forceps. One specimen recovered in this way was found on microscopic examination to have a collar of bowel mucosa adhering to the junction of the thin anterior portion with the thick posterior portion (see figure).

Hexylresorcinol was chosen as the most suitable of the available anthelmintics (Lamson et al. 1931) and after a short period of starvation and purgation 0·9 g. of the drug was given by mouth. This resulted in the excretion of an enormous number of dead worms in the succeeding few days, and the abdominal pain and tenesmus disappeared. After a week, as the patient was still having about 4 bowel movements daily the drug was given again with a similar result; this also failed to stop the diarrhœa, so after another week a further dose, this time of 1·6 g., was given. On this occasion daily examination of blood-films revealed that the eosinophilia, which was 13% on the day of treatment, rose to a peak of 21·5% two days later and declined thereafter. No toxic manifestations occurred.

The patient was discharged at this stage and when seen two months later was completely free from diarrhœa and abdominal pain, but still complained of a little tiredness and breathlessness, although these were much less than before admission. Her stool still contained a large number of ova, but the excretion of dead worms had ceased. Specimens of fæces from her two daughters were examined and both were found to be excreting ova in fairly large numbers, especially the younger, aged 18 months, who was quite heavily infested. Neither had any symptoms referable to the condition.



Male *T. trichiura* 3 cm. long, the neck accounting for 2·1 cm. of the length. The body is in a spiral [illegible] alimentary canal and testis can be [illegible]. Surrounding the junction of neck and body is a fragment of intestinal mucosa, in which the [illegible] (Photo by Dr A. H. Cruickshank.) [illegible]

DISCUSSION

Little information exists regarding the incidence of trichocephalus infestation in this country, which is not surprising considering how seldom it produces symptoms. Still (1918) found the worm at autopsy in the cæcum of 8% of children but he never saw more than three or four worms in a single case and was never able to diagnose the condition during life. He also records that there was invariably a coexisting infestation with threadworms. Manson-Bahr (1938) has found the ova in the stools of children in Kent. The incidence is probably much less now than it was at the time of Still's observations owing to improvements in sanitation in the past 20 years; in the north-east of Scotland it must be very low since in Aberdeen the ova have not been seen in the routine microscopic examination of stools, nor the worms observed in the intestine at autopsy, for the last 5 years.

It was impossible to trace the original source of the infestation in the case described, but the circumstances which brought about the gross degree of infestation are interesting.

The patient has been living in her present house in a small country town for the past 10 years, and until 3 years ago the disposal of excreta was effected by a pail closet which was emptied into a hole dug in the garden adjoining the house. In the same part of the garden vegetables were grown, including a large number of lettuces. The patient confessed to a great liking for lettuces, and was in the habit of eating some almost every day while they were in season, thus probably reinfesting herself regularly and heavily. The children did not share her liking for lettuce and are less heavily infested. The husband, who ate no lettuce, is on active service and not available for examination.

It is impossible to assess the number of worms harboured by the patient on admission, but it is estimated that over 1000 were removed during treatment. Estimation of the number of worms present by means of egg counts on fæces is not of value, since the number of eggs per female worm varies inversely as the number of worms present (Miller 1939).

It is usually taught that whipworms themselves produce no symptoms, although they are commonly found along with other parasites, such as the threadworm, ascaris or the hookworm, which may produce symptoms. Swartzwelder (1939), however, analysed 81 cases in which symptoms were considered to be attributable to a pure whipworm infestation. He found that the commonest symptoms were abdominal pain, usually right-sided, and vomiting. Constipation was commoner than diarrhœa, which was noted in only 5 cases. Most of the cases showed some anæmia, but a hæmoglobin of less than 70% was uncommon. Eosinophilia of over 6% was present in 6 out of 81 cases. In the case reported here, the absence of other ascertainable cause for the diarrhœa, its amelioration after

THE LANCET

LONDON SATURDAY, JULY 25, 1942

DISCOVERING TUBERCLE

Overwhelming evidence is now available showing that radiological changes usually precede both physical signs and symptoms of tuberculosis Thus if early diagnosis is to be the rule rather than the exception, it follows that periodical routine chest radiography will have to be applied to susceptible groups of the population on a very large scale Convenience and cost make miniature screen photography the method of choice, provided a sufficient degree of accuracy is obtainable In a recent review of 20,000 screen miniatures in the RAF, Trail says[1] he obtained smooth and efficient working with 100 examinations per hour, modern American equipment was used, and in the miniature films which showed lung abnormalities the picture was almost always sharper than on the following large film He admits that the most he expected of the miniature film was to reveal abnormality requiring further investigation—clinical, pathological or radiological His review showed that of 20,000 young men who had made no complaint and who had passed the routine medical examination 54 (0 27%) had active and 67 (0 33%) inactive pulmonary tuberculosis In our present issue Crawford analyses 300 consecutive Service cases admitted to a sanatorium in recent months, a considerable majority of these cases presented obvious symptoms of active tuberculosis within a year of being passed fit for service and most of them were no longer " early " cases at the time of diagnosis In Crawford's opinion, based on history and radiological evidence, two thirds of these cases could have been diagnosed by radiological examination at the time of enlistment Although unamenable to scientific proof there seems no reason to doubt his conclusion that " though the criteria for further investigations usually adopted by medical boards are important, they are in themselves unreliable as a means of detection of all but a small proportion of the total number suffering from pulmonary tuberculosis " If then radiological investigation is the only reliable procedure for the detection of clinically unsuspected cases of pulmonary tuberculosis, he is surely justified in hoping that the Horder Committee will now reconsider the problem in the light of his own and other recent findings

We suspect the recent white paper (Cmd 6353, 1*d*) of undue optimism in its inference that as about one per cent of recruits are rejected on grounds of tuberculosis only one or two per thousand are left to be detected after recruitment by miniature radiography Available evidence makes it sadly unlikely that 10 out of 11 or 12 cases of pulmonary tuberculosis could possibly be detected by clinical methods alone While it would hardly be fair to ask for the number of men discharged from the forces on account of tuberculosis it would be useful to know how the percentage of cases of tubercle discovered in the British Army compares with that of the Canadian Forces in this country, the latter having been examined radiologically as well as clinically The Minister of Health in his review of the nation's health on June 30 remarked that we must review our approach to tuberculosis and give greater practical effect to the need for early diagnosis, he described miniature radiography as a new and useful weapon of which the fullest advantage should be taken, and it is encouraging to know that sets of apparatus are already on order from manufacturers in this country and in America Routine radiological examination of large groups of people has thus entered the sphere of practical politics, when it has been extensively applied we can confidently predict the detection of large numbers of symptomless and signless patients, and the first step in the weeding out of tuberculosis will have been taken. What we are to do with them when found is another matter Cases of active disease will mostly require institutional treatment, and we are short of sanatorium beds and nurses Other cases, including the inactive or doubtfully active lesions, will get well if relieved from industrial strain and freed from economic want That is a problem of social medicine in its purest form

MENTAL NURSING

At the instance of Lord Latham the Upper House has considered[1] in many of its aspects the exclusion of mental nurses from the purview of the Rushcliffe Committee and it would be well for all concerned to ponder the 20 columns of *Hansard* for July 8 recording the debate Equally worthy of close study is the story of a remarkable piece of quiet conciliation whose continuance coloured the claim to separate consideration In 1919, it may be recalled, conditions of service of nurses in mental hospitals were poor In some places the weekly hours of work amounted to as much as 70 and rates of pay had never been stabilised The nurses not unnaturally were dissatisfied and made their opinion known through the Asylum Workers Union which had been founded in 1910 In February 1919, largely thanks to Thomas Field, then chairman of the Bucks mental hospital visiting committee, a federation of representatives of visiting committees, known as the Mental Hospitals Association, was formed, and in the following March this body, with representatives of the union, established the Joint Conciliation Committee upon which employers and employees were equally represented This joint committee, in effect a Whitley council, has remained steadily active until now Among the more important milestones in its career are the stabilisation of rates of pay after the 1914–18 war and the introduction, in 1935, of the 54-hour week for mental nurses with two clear days off duty in each week There still remained, however, a difference in the rate of pay between rural and urban areas The efforts of the joint committee to remedy this culminated in October, 1941, when they published recommendations about conditions of service and pay which had crystallised from 19 years' experience of amicable and continuous negotiations.

During that period the manifold aspects of mental nursing had been considered as they were presented in individual cases from hospitals all over the country These consolidated recommendations were felt to be so important in official circles that their acceptance by visiting committees and mental hospital staffs was made a condition for the enforcement of the Mental Nurses (employment and offences) Order 1941, issued partial destruction of the parasites, and the observation of a worm with its head apparently buried in an inflamed area of colonic mucosa, strongly suggest that the diarrhœa was the result of the infestation Judging from the degree of anæmia, the diarrhœa and the sigmoidoscopic findings, this case seems to have been more heavily infested than the average, with the more distal part of the large bowel affected to an unusual extent

Reviews of Books

Year Book of Neurology, Psychiatry, and Endocrinology, 1941

Editors HANS H REESE, M D, NOLAN D C LEWIS, M D, ELMER L SEVRINGHAUS, M D Chicago Year Book Publishers, London H K Lewis Pp 768 16*s* 6*d*

THE editors of this invaluable compendium give little or no space to articles which merely turn over old furrows The endocrinology section is therefore the most lively and rich in material, the section on neurology is of equal length but contains many articles which might with as much propriety have been included in the psychiatric section shorter by a third than either of the other two Inevitably the European contributions are scanty compared with those of earlier volumes, and some of them date from the latter part of 1940, but the American and British output for 1941 is fully represented, and the clinician or research worker, bereft of his customary abstracting journals can turn with confidence and some gratitude to this conspectus The editorial notes are concise and plentiful—except in the psychiatric section—and helpfully critical, the abstracts are competent and 130 figures and illustrations amplify the text A fifth of the psychiatric section is devoted to military aspects In the endocrinology section Professor Sevringhaus lays timely emphasis on the need for conservative diagnosis of endocrine disorders, quantitative methods should be employed and the time is at hand, he suggests to insist that these potent materials be used with due respect for what good or harm they may do

Fractures and Dislocations

KENNETH M LEWIS, M D, F A C S, assistant clinical professor of surgery, New York University College of Medicine London Humphrey Milford, Oxford University Press (Medical Outline Series) Pp 217 12*s* 6*d*

IN this brief account of his methods of treating fractures Dr Lewis sets out to simplify description by tabulating the whole work This does not make for easy reading and a beginner might find it incomprehensible He describes in detail the mechanical aspects of fracture treatment, but there is no discussion of alternative methods—which is a pity, for many of his methods will not prove generally acceptable Thus he recommends carrying a pail of water for the stiff elbow, Thomas splint traction for humeral neck fractures, with no differentiation of adduction and abduction types of fracture, the use of Kirschner wire traction in many fractures of the upper extremity, and resumption of weight bearing six weeks after a dislocation of the hip Blind nailing is recommended for all intracapsular fractures of the neck of the femur, irrespective of type, and without discussion of the complications which may follow these fractures Local infiltration "about the fracture" is advised for anæsthesia in reducing Colles fractures, but no mention is made of the infiltration of the hæmatoma, which is essential if adequate anæsthesia is to be obtained This book, giving as it does precise and formal directions for almost all types of injury should be useful to the inexperienced who may at short notice, in these days of sudden violence, be called *on to treat fractures*

The Blood Bank and Technique and Therapeutics of Transfusions

ROBERT A KILDUFFE, M D, F A S C P, director of laboratories, Atlantic City Hospital, M DEBAKEY, M D, assistant professor of surgery, Tulane University of Louisiana London Henry Kimpton Pp 558 37*s* 6*d*

THE appearance of this book is timely Its scope is wide, for it covers in detail in sixteen chapters the field of intravenous therapy with blood or blood products, including the military aspects, the rationale and the pitfalls of transfusion, blood-grouping, the cleaning and maintenance of apparatus, the technical procedures involved in running blood banks and the production of wet and dried plasma, and the history of transfusion The authors have attempted to sift and digest an immense volume of published writings Consequently parts of the book are uneven, and the reader is presented with a mass of facts, many of them contradictory, without being guided as to which to accept and which to reject *Particularly is this so in the technical sections* where numerous different methods and types of apparatus, generously illustrated, are described Some statements are surprising for instance, that 3 physicians and suitable assistants working for four hours can bleed 32 donors, removing up to 800 c cm from each It is apparent that the authors have not yet gained experience in the large-scale collection of blood and the preparation of *blood products, but these are only minor* blemishes in a well-produced and informative book

Clinical Aspects of the Electrocardiogram

Including the Cardiac Arrhythmias (4th ed) HAROLD E B PARDEE, M D New York Paul B Hoeber, London H K Lewis Pp 434 35*s*

IN this book the possible variations in the cardiogram in disease are described in detail but seldom illustrated The theory of the cardiogram is also fully discussed, much attention being given to mathematical treatment of the electrical axis and to consideration of vectorgrams These aspects although of great interest to the cardiologist have little immediate application to clinical medicine Dr Pardee's views on the best sites for chest leads and on the naming of the peaks in aberrant types of QRS complexes deserve attention Specially useful is the chapter on the construction and operation of the electrocardiograph

Encephalitis A Clinical Study

JOSEPHINE B NEAL, M D, Sc D, F A C P, associate director of the bureau of laboratories, Department of Health, New York, clinical professor of neurology, College of Physicians and Surgeons, Columbia University New York Grune and Stratton Pp 562

DR Neal is well equipped to lead a team of six distinguished collaborators, for she has been studying encephalitis since she became secretary of the Matheson commission in 1918 Her own contributions, which are entirely clinical, include a description of the primary and secondary virus infections of the central nervous system, a full account of the course of epidemic encephalitis and a short and conservative chapter on its treatment Dr Tracy Putnam gives a short account of his original work on the surgical amelioration of symptoms, usually undertaken in hope and abandoned in despair A section on epidemiology is written by Dr Muckenfuss, and on psychiatric complications in adults and children by Dr Rosner and Dr Bender The most important part of the book, by Dr L D Stevenson, deals exhaustively with the pathology of every form of encephalitis yet recognised in man He even includes such widely differing and apparently irrelevant subjects as disseminated sclerosis, arsenical encephalopathy, Jamaica ginger paralysis, and anoxæmia Publication is timely for the book brings together a fund of knowledge of diseases which acquire especial significance in time of war

candidate feel he is being put through an inquisition or that his fitness is being unfairly judged by people ready to read much meaning into every look and movement. During the three days he is at the centre he will have opportunities of showing how he behaves when he is tired, when he has to devise ways of overcoming natural obstacles, when he is discussing plans and problems with his fellow-soldiers. His intelligence, measured by the customary psychological tests, will also be assessed by combatant officers who see him dealing with practical situations that they have contrived for him—situations in some ways similar to those which will confront him in the field. The psychiatrist will interview him, unless he is obviously too good or too bad a candidate to need any such examination, and will appraise his personality; any neurotic traits that he may have must be set against his other qualities, and a fair judgment made as to his stability and fitness to lead others in the stressful conditions of modern warfare. But these are not the final judgments. The president of the board is responsible for the decision that the candidate may proceed to an officer cadet training unit or not.

Standardised psychological procedures play only a small part in this whole. Tests of personality are used, but modestly; the results are not taken at face value but passed on to the psychiatrist who must evaluate them in the light of his clinical experience and findings. It would be dangerous to give a lot of weight to the results of projection tests and other such procedures while they are still somewhat equivocal—they can be double-edged tools. If inexperienced persons without thorough psychological training were to be allowed to pronounce upon them, and these interpretations were taken seriously, it would be devastating. But this is a branch of psychology in which there has lately been much activity and methods are likely to become increasingly reliable. The same principles must be followed in their use as are employed for selection of men generally; thus no procedure should be adopted wholesale until its value has been critically checked against the results of the test which real life affords. Only when predictions based on selecting procedures are shown to tally with the success chosen men subsequently show in the job should such procedures be given their letters of credit.

Annotations

BITTNER AND HIS FORERUNNERS

Dr. Georgiana Bonser, holding a Brotherton fellowship in cancer research at Leeds, has confirmed J. J. Bittner's remarkable observation that mice babies of certain inbred strains derive from their mothers' milk something that promotes the development of breast cancer. Bittner suggested that this factor is a virus. Bonser transferred newborn male sucklings of RIII strain (high breast cancer) mothers to mothers of CBA strain (low breast cancer) and vice versa before injecting them with triphenylethylene, and she has noted an almost complete reversal of the incidence of mammary cancer appropriate to the strain. Previously any form of œstrogenic treatment had failed to induce mammary cancer in males of an immune strain. Some CBA females suckled by RIII foster mothers have developed spontaneous breast cancers for the first time in the experience of the laboratory. Prof. R. D. Passey in his report[1] to the Yorkshire Council laments that Bittner's discovery seems at the moment to make the cancer problem even more complicated than had been supposed previously. It certainly offers unexpected support to the virus theory of the cause of cancer, but seen in perspective it is a natural sequence of a technique which has enabled the observer to isolate at will and study separately all the factors that play a part in the development of tumours.

In his foreword to the report Sir Harold Mackintosh says it is broadly true that cancer research was not seriously attempted until after the last war. But it is a pity to forget the probing mind of Rudolf Virchow or to overlook that all but one of the clues to the cause of cancer which we now possess were discovered by 1917. Virchow established the foundations of our knowledge of the cellular basis of cancer and laid the foundation for its micro-anatomical classification; he drew attention perpetually to the prolonged and chronic nature of the stimuli which preceded cancerous change. Ribbert revealed the autonomous nature of tumours; they grow *aus sich heraus*, as he put it. Pott as long ago as 1770 associated the prolonged exposure of chimney sweeps to soot with the high rate and early incidence of scrotal cancer in young men following this occupation. He sought to get legislation to prevent this occupational disease. Murray in 1911 showed that mice in whose ancestry cancer of the mamma has occurred not further back than the grandmothers are more liable to develop the disease than mice whose cancer ancestry is more remote. Yamagiwa and Itchikawa combined Pott's observation with Virchow's teaching on the chronic nature of the stimulus required and applied tar for months on end to the skin of mice and rabbits. They proved in 1917 that cancer could be produced at will by a chemical agent. Rous in 1911 transmitted fowl sarcomas by means of cell-free bacteria-free filtrates of tumour material. Loeb in 1916 combined Murray's observation of a hereditary tendency in mammary cancer of mice with a brilliant guess that ovarian secretion had something to do with it. By removing the ovaries of very young female mice of a strain inbred to develop mammary cancer, he prevented the incidence in ovariectomised mice of this disease in the expected high numbers.

These clues have been relentlessly followed up. Kennaway divined the nature of the carcinogenic factor in tar (it must be composed of carbon and hydrogen) and with Cook synthesised benzpyrene and other carcinogenic chemicals. They showed also the possibility of a similar synthesis in the body by the production of methylcholanthrene. Lacassagne took the ovarian hormone folliculin and proved that Loeb's ovarian influence was due to the secretion of this substance. Rous combined a newly discovered filtrable agent (the Shope papilloma) with a chemical agent (tar); together they produced a quality and vigour of tumour growth which never results from either alone. After Loeb had started to unravel the factors responsible for the development of hereditary mammary cancer by showing that that disease failed to develop in the absence of an ovary, there still remained an apparent hereditary influence. The discovery of the nature of this influence is the only really new clue since 1917. In 1937 Bittner and Little proved that it resided in and was transmitted in the mother's milk. If young mice of a high cancer lineage were removed at birth from all contact, especially suckling, with their mothers and nursed by mice of a strain free from mammary cancer, they failed to develop the disease even though they were thoroughly treated with œstrin. The mother's milk of the high cancer strain contained the essential factor. But Bittner has shown also the existence of a true hereditary influence transmitted as well by the father as by the mother. These long-established lines of research are still the mainstay of cancer research.

[1] Yorkshire Council of the British Empire Cancer Campaign: 16th annual report (1941–42) from the department of experimental pathology and cancer research, University of Leeds.

by the Minister of Health under the Defence (general) Regulations of 1939 (commonly known as the Standstill Order). It was thus ensured that no nurse would be obliged to continue in the service of a mental hospital unless conditions and pay were favourable enough to meet with Government approval. The recommendations perpetuate the 54 hour week as the standard maximum and provide, in the case of male nurses, for a commencing (gross) salary of £2 10*s* a week, for women nurses of £2 per week, rising to £4 3*s* 6*d* and £3 13*s* 6*d*. These rates do not include war bonuses or increments for passing examinations and charges are made to the residents for board and lodging. Official blessing would not, of course, have been given to these conditions unless they were reasonably widely accepted; and in fact nearly every mental hospital staff is represented by a local branch of what is now the Mental Hospitals and Institutional Workers Union, while of the 76 local *authorities in England and Wales which manage* mental hospitals 69 are members of the Mental Hospitals Association. The joint committee is thus a negotiating body representing nearly 20,000 mental nurses who are union members out of a total estimated at 30,000, and 69 local authorities who are responsible for some 86 mental hospitals out of a total of a little more than 100. It is greatly to the credit of the governing authorities of mental hospitals and their staffs that they should have evolved a good machine for solving their own problems.

Nevertheless nursing is a national problem and mental nursing is only one aspect of the care of the sick. Indeed everything which tends to set the mental patient apart from other sick people is reactionary and smacking of the old fancy of diabolic possession. There will, perhaps, always be room for a conciliatory body specially devoted to the needs of the mental nurse, but this must form part of a considered scheme covering the needs of nurses as a whole. Whether the mental nurse is at present regarded merely as an attendant, as Lord MANDERS seems to think, is beside the point. If she is in a hospital or a ward where the experience of general physical illness is considerable, and if the matron and the sister tutor know their job, the nurse becomes capable in her profession; if she is kept for years in a chronic ward, lacking the stimulus of refresher courses and a change of experience, she declines into an attendant; who would not? Nor is it possible to make dogmatic assertions about the intellectual standard of mental nurses; in most places the rank and file take the RMPA instead of the State examination, and the standard of the latter is admittedly more exacting. There are evidently grounds for a levelling up of standards, but not for isolating mental nursing from all other branches of the profession. The care of mental patients may demand special qualities in the nurse, but mental patients are not immune from the physical illnesses whose treatment requires adequate training in general nursing. Contrariwise, the mental problems of patients in general hospitals are beginning to receive attention and thus the general nurse needs experience of mental hospital work as part of her training. Some method of interchange between nurses in general and mental hospitals would be of benefit to all parties, including the patients. Oxford and Exeter have tried it out on a small scale, but it can hardly be achieved on a large one until rates of pay, pensions and conditions of service in the two branches are dealt with comprehensively by the same body. We can hardly be wrong, following the lead given by the Athlone Committee, in asking a subcommittee of the Rushcliffe Committee to consider (without prejudice to existing agreements) the position of mental nurses, just as other subcommittees are considering the position of health visitors and school nurses. The Mental Hospitals Association and the Workers Union would place their knowledge and experience at the service of this mental nursing subcommittee, which would be amply represented on the main committee and work in collaboration with it. The past would thus be honoured without jeopardising the future.

LEARNING TO CHOOSE

Fas est et ab hoste doceri. It has been customary in the German Army to use psychological investigations to select officers and specialists; and a huge literature has accumulated[1] round the subject of "psychological warfare." Much emphasis is laid on the psychologist's estimate of a candidate's personality. The history of his life, with his ambitions, interests and successes, is studied and his behaviour analysed: what does his facial expression betray about his character, what are his gestures, what can be learned from his voice, his demeanour, his handwriting? His intelligence, his imaginative power (tested by asking him to describe the story which some pictures tell) and his persistence are assessed. His response to commands and capacity to lead and direct others must also be judged by practical tests. How much of this procedure, elaborately described in the technical journals, is still employed, what modifications and additions are customary, is unknown. But it is clear that there was much controversy about the psychologists' share in selecting officers and specialists, not only in the Army but also in the Luftwaffe, and that there were some sudden changes of policy. It is also clear that the final say rested with the commanding officer, not with the examining psychologists.

It is not to be supposed that the Germans alone had heard of applied psychology. Industrial psychology, with which all this has a close affinity, has been most actively pursued in our own country, in the United States, and in Russia and France. All the major participants in the 1914–18 war used tests for aviation pilots, hydrophone operators and other specialists. We can hardly have forgotten that, nor have failed to profit by the advances made since 1918 in vocational and other branches of psychology. Is there then anything for us to learn from the enemy? We can perhaps let him teach us that officers are specialists, about whose selection we should take great pains and use whatever aid psychology can afford us. We can also let him unwittingly teach us, when we scrutinise critically what he writes about the matter, that psychology cannot yet afford us much help in judging character and that a pretentious array of "characterological" tests is a dangerously uncertain way of deciding who is fit to be given the training of an officer. There is certainly no need for us to play the sedulous ape in this, nor do we. The procedure at one of our officer selection centres is not likely to make the some cases of so called idiopathic steatorrhœa arise from a transitory giardial infection. They quote the fatal case in an adult reported from Dublin two years ago[8] and record the case of a boy aged 9 in whom chronic steatorrhœa was associated with stunting of growth, anæmia and radiological evidence of disorganisation of the mucous membrane of the lower part of the small intestine. In this boy encysted forms of *Giardia lamblia* were found in mucous shreds obtained after severe purgation though no parasites were seen in the ordinary stool. Miller[9] has noted the finding of giardia in the stools of cases of cœliac disease, and Manson-Bahr[10] records examples of giardiasis which, as far as the stools were concerned, resembled tropical sprue. The protozoa are provided with sucking discs by which they attach themselves to the mucosa of the ileum, and if present in sufficient numbers they might interfere with fat-absorption by the villi. There is no suggestion, however, that the Dublin cases were infested to this degree. It seems strange, if some cases called cœliac disease arise from giardiasis, that this condition is not more often seen in the tropics. The effect of mepacrine in such cases may not settle the question, for if O'Donovan and his colleagues are right damage to the small gut may remain after the giardia has died out. Certainly in their case no striking improvement has followed disappearance of the parasite. There can be no certainty about this hypothesis until a sufficient number of cases of cœliac disease have been studied in their early stages. Meanwhile, it seems fairly certain that, like its relative *Giardia muris* in rats, *Giardia lamblia* is a potential source of harm.

[1] German Psychological Warfare. Committee for National Morale, New York, 1941.

THRESHOLD FLUOROSIS

THE question why the inhabitants of Tristan da Cunha have such excellent teeth has been used as a test case for every theory regarding the ætiology of dental caries. Yet another possible answer has now been given by Sognnaes.[11] Instead of the usual rapid inspection of the island's inhabitants during the few hours of a steamer's call, he spent some weeks on the island and had ample time for observing the environmental conditions which might affect dental structure. He confirmed the remarkable freedom from dental caries, but he also noted the white spots characteristic of a very mild degree of dental fluorosis, which he has aptly described as "threshold" fluorosis. All the water used by the islanders came from a spring containing 0 2 part per million of fluorine, and in addition their dietary included much fish, whose tissues contain ten times as much fluorine as that of land animals. Later, on return to the United States, Sognnaes and Armstrong[12] determined the fluorine content of teeth obtained in Tristan da Cunha. They found that deciduous teeth from the island all had a definitely higher fluorine content than corresponding non-fluorosed sound teeth from Minnesota analysed by the same method. In the islanders' permanent dentition Sognnaes had noted a greater degree of mottling in the front teeth than in the molars, and the most fluorine and least caries were also found in the front teeth. These results confirm the observations of American[13] and British[14] observers on the relative immunity to dental caries associated with drinking-water containing fluorine.

On another page Kemp, Murray and Wilson raise the question whether the quantities of fluorine commonly found in British drinking-waters, sufficient to produce dental fluorosis, will also produce skeletal changes during the growing period which may lead to incapacity later in life. In parts of the world—Madras and South Africa—where the inhabitants drink water of high fluorine content, skeletal changes have been reported consisting of a progressive sclerosis of all the bones resembling that seen in industrial fluorine poisoning in cryolite workers. In the present investigation in Oxfordshire villages and at Maldon in Essex spinal changes of the adolescent kyphosis type were found associated with mottled teeth, but the correlation was by no means definite, and Spira[15] has lately demonstrated that more than 22% of a mixed group of British adults had some degree of dental mottling. A much larger controlled series, watched for years, will be required to settle whether fluorosis must be considered one of the causes of spondylosis deformans.

THE VEINS AND THE MUSCLES

WE are still ignorant of the whole story of how the blood is returned to the heart by the veins but there is good evidence, as Yandell Henderson[16] shows, of the important part played by muscular contraction. During exercise the rôle of muscular contraction is obvious; each muscle acts as a peripheral pump, or as Henderson neatly describes it a booster—i e a pump used to increase the pressure of fluids. In this way the five fold increase in the output of the heart which occurs during exercise is largely accounted for. At rest the same mechanism is probably at work the difference being a quantitative and a qualitative one. Two factors come into play here. In the maintenance of tonus in the muscles at rest a variable if small, number of fibres in every muscle are contracting all the time, and the alternating contraction and relaxation of these minute peripheral pumps or boosters in the muscles is largely responsible for maintaining the flow of blood in the veins. The other factor which assists in this process is the difference between the intramuscular pressure, higher than atmospheric pressure as the result of muscle tonus, and the subatmospheric pressure in the thorax. Thus even at rest there are adequate forces present in health to ensure the return of the venous blood to the heart. A necessary corollary is that these forces are to a large extent dependent on the state of the spinal centres responsible for the maintenance of tonus in the somatic muscles. Skeletal muscle has practically no intrinsic activity; as Henderson expresses it, their behaviour is imposed on them from the central nervous system. The bearing of this on the ætiology and treatment of shock is obvious. In shock, whatever the precipitating factor may be—whether trauma, infection or pain—there is failure on the part of centres in the nervous system. At one time it was supposed that this failure involved primarily the vasomotor centres, but it now seems as if the fault lies, at least in part, in the centres controlling the skeletal muscles, and that the failure of the peripheral circulation is due as much, if not more, to slowing of the blood-stream in the veins in the flaccid muscles as to pooling of the blood in the arteries or arterioles in the splanchnic area or skin, now recognised to be such a large blood depot. As a result of this slowing of the blood stream anoxia gradually develops in the tissues, a process which in turn results in increasing permeability of the capillary walls with oozing out of serum and probably some corpuscles, so that a state of oligæmia develops. In other words we have the triad of shock—bradyrhœa, anoxia, and oligæmia. Reports on the treatment of shock lend considerable support to this hypothesis. In shock unaccompanied by hæmorrhage the best results are obtained by the administration of serum; where hæmorrhage is severe whole blood must be administered. In both types of case the administration of oxygen is essential. Where the shock is unaccompanied by bleeding, restoration of the circulating blood-volume, adequately oxygenated, is sufficient, along with the other essential lines of treatment such as

SOCIAL MEDICINE GETS A CHAIR

A NEW spirit is stirring in medicine, as the focus of attention swings from the negative to the positive aspects of health. The cure of disease has fascinated us for centuries, partly because success when it comes is so immediately rewarding and partly because one sick man makes a more dramatic appeal than ninety-nine not obviously in danger. Moreover, in the excitement of research it is possible to lose sight of the whole in enthusiasm for the part. That an impulse to share knowledge is abroad is manifest in proposals for health centres, for regional cancer control, and in the foundation of such units as the London Hospital department of psychiatry and neurology. Alongside this desire to pool knowledge a wider conception of the functions of medicine is growing up. This is no sudden awakening to the latent possibilities of preventive medicine, for we have been aware of those long enough: advances in public health such as vaccination, purification of water and rising standards in public and personal cleanliness have all helped to reduce disease. It is rather a growing sense of social responsibility among doctors—a realisation that since many diseases depend on social conditions it is the business of the profession to study those conditions and propose remedies. This is why the foundation, by the Nuffield Provincial Hospitals Trust, of a professorship and institute of social medicine at Oxford University is such a landmark. The trust proposes to devote £10,000 a year, for ten years in the first instance, to this purpose. The task of the institute will be to investigate the influence of social, genetic, environmental and domestic factors on the incidence of disease, and to seek and promote the protection of the individual and the community against forces hindering the development and maintenance of full mental and physical capacity. If the university wishes, the institute will also provide instruction in social medicine for medical students and doctors approved by the board of the university faculty of medicine. It is to be hoped that the opportunity will be taken to establish a nursing section in the new institute, for the progress of social medicine depends on public as well as medical education, and in this the public health nurse of the future, by whatever name she is known, must play an increasing part both as an investigator and a teacher. The institute will be administered by a committee on which the trust will be represented by six members who will help to link up the institute with research institutions elsewhere.

OIL AND PETROL IN THE LUNG

FLUIDS which intensely irritate the bronchial mucous membrane may be partly removed by coughing, but the paroxysms may aggravate the risk of suffocation, and in the case of volatile poisons the rate of absorption is so great that coughing does not appreciably reduce the risk of remote toxic effects. This is illustrated in the case reported recently by Cope[1] of aspiration of petrol into the lungs. Attempts to cough it up seem to have been hampered by acute dyspnœa, and unconsciousness supervened in a few seconds. The lung and even the pleura is liable to sustain considerable damage in such cases. Machle[2] in a review of gasoline intoxication mentions hyperæmia, petechial hæmorrhages, subpleural extravasations and gross pulmonary hæmorrhages in which the alveoli may be filled and the epithelium become necrotic in entire lobules. Bronchitis is common and several instances of pleural effusion have been recorded. Poppyseed oil, the base of iodised oil (*B.P.*), is often injected into the lung as a diagnostic agent and occasionally as a remedy. Cases of iodism are reported from time to time after the use of this preparation, but the oil itself appears to give no trouble, even though years may elapse before the last traces of it are removed by coughing. Yet neurologists are showing increasing reluctance to inject it into the spinal theca because signs of irritation of nerve trunks are occasionally seen, so that it may be premature to conclude that iodised oil is harmless in the lungs. The reputation of liquid paraffin as a bland mechanical laxative has been questioned by American investigators,[3] and it has been shown to cause pneumonia, and even the formation of paraffinoma when aspirated into the lungs. Kaplan[4] states that since 1925 a total of 411 cases of oil pneumonia have been reported, and that in 68% of the cases liquid paraffin was wholly or partly responsible. By applying a simple histochemical technique, he was able to prove, in a case of oil pneumonia under his care, that liquid paraffin and cod-liver oil were present in the lung, which showed the "typical structure of an acute and chronic interstitial type of oil pneumonia." The clinical picture and pathological findings in cases of petroleum aspiration on the one hand and liquid-paraffin aspiration on the other are evidently closely related not only to the intrinsic toxicity of the material but also to the physical and chemical properties of the different types of oils, and these in turn determine the rate of absorption through the lung. In recent years there has been a considerable increase in the number of cases of unresolved pneumonia, associated, it seems, with the use of the sulphonamides; but the widespread habit of taking liquid paraffin as a laxative, and the administration of cod-liver and other vitaminised oils to children should be borne in mind when considering the differential diagnosis. Moreover these oils are often inflicted on debilitated and prostrate patients by force majeure, and for these aspiration into the lungs is a real danger.

EVEN THE GIARDIA MAY TURN

INFESTATION with *Giardia lamblia* is almost universal among the natives of India, Egypt and Iraq, and there it seems as a rule a harmless guest. Elsewhere it is also common—in Norway, for instance, where Boe[5] has lately demonstrated that at least half of a fair sample of the healthy population carry some intestinal protozoon, in 5% the parasite was the giardia. A variety of symptoms have been ascribed to giardiasis in Latin America and the United States but it has been difficult to decide whether this is not merely a secondary invader which gains a footing when other causes of ill health have rendered the intestinal or biliary tract suitable for its multiplication. In Norway patients with diseased gall-bladders were found to be more often infested than healthy people, but otherwise the clinical findings were inconclusive. The introduction of a specific parasiticide against giardia—mepacrine hydrochloride ('Atebrin')—seemed likely to settle the question of its pathogenicity. At the Mayo Clinic Kyser[6] analysed the symptoms encountered in 100 people with giardia in the stools and the effect of treatment with mepacrine in some of them. In 11 cases the giardiasis was asymptomatic. The main symptoms found in the rest were diarrhœa, with 2–20 loose stools daily, pain or discomfort in the upper or less commonly lower abdomen, nervous symptoms such as tiredness and irritability, intermittent fever and vomiting attacks. Of these, diarrhœa and abdominal discomfort occurred in nearly two-thirds of the patients; the other symptoms were rarer and their connexion with the parasite less definite. In 35 patients a five-day course of 1 gramme of mepacrine three times a day was given, followed by re-examination of the stools. In all but one the parasites disappeared from the stools, and in 13 the symptoms were completely relieved for a significant period. O'Donovan, McGrath and Boland[7] of Dublin have raised the question whether

THIRTY YEARS OF NATIONAL HEALTH INSURANCE

R W Harris o b e

HAIRMAN OF THE LONDON MEDICAL SERVICE SUBCOMMITTEE,
OMETIME AN ASSISTANT SECRETARY IN THE MINISTRY OF HEALTH

THE Editor—doubtless having recalled that I am still ctively associated with the scheme of National Health nsurance and that my association goes back as far as the day of the first reading of the bill in 1911—has reminded me that today the fifteenth of July is the thirtieth nniversary of the coming into operation of the scheme, and has asked me to jot down a few notes on the subject

Sir Arthur Salter is speaking in the House of Commons n secret session on the shipping situation He will have no time to recall that he was Charles Masterman's private ecretary in 1912, sitting up half the night drafting answers to a record number of questions in an attempt to atisfy the voracious appetite of the House of Commons of that day These hungry members were actually being egged on by doctors who did not like the Insurance Act—did not like it at all—and there was still time on the fifteenth of July 1912, to force or worry Parliament into moulding the measure more to their liking, or better still to sweep the whole thing back into the obscurity from which it should never have emerged , that was how the medical profession seemed to feel at that time

There was still time , for the fifteenth of July was only the beginning of "stamp-licking" Money, through the medium of deductions from wages and stamps affixed to cards must flow into the national coffers for six months before the doctors were to come on the scene January, 1913, was the time for the real "opening" so far as the doctors were concerned, and in the meantime they could continue to enjoy the privileges of looking after the working population with all the advantages and disadvantages attaching to private practice And when the appointed day in January came, the long gathering storm clouds just quietly went elsewhere, the threats of a "strike" of the whole medical profession—that is, I'm afraid what vulgar people called it—subsided, the Exchequer had found another half a crown for the capitation fee, and the signed statements taken from nearly the whole profession, refusing to take office under the scheme, were unceremoniously consigned to the BMA waste-paper baskets National health insurance was an accomplished fact The thing was working

The Lord President of the Council is too busy today with the Home Front to recall the fifteenth of July, 1912, when a certain youthful John Anderson, only recently arrived at the Insurance Commission from the Colonial Office was dealing with minor problems in that masterful way of his, and was soon to leap forward to be secretary of the commission, dominating the scene , and thence onwards to many increasingly important fields of activity, impressing on them all the hall-mark of his personality Sir Maurice Gwyer is too absorbed in the problems confronting him as Lord Chief Justice of India to recall the days of 1912 when he was drafting with consummate patience the hundred and one regulations and orders which were to make the NHI scheme function He may still chuckle about the "Henry the Eighth" clause which some inspired person had put into the bill, enabling the Insurance Commissioners to do anything necessary to make the scheme work It was good stuff, even if it did lead Lord Hewart to write down some nasty things about bureaucrats

These three notable figures of today, Anderson, Gwyer, and Salter, are but a fraction of the great number of eminent people who were associated with the national health insurance scheme at its inception This is not the place for me to recall the men—notably that great figure, Sir Robert Morant—who were responsible for the launching of this scheme and for seeing it through its early years, but I must find space to say that my colleague W J Braithwaite, with whom I had the honour to work during the years 1911–12, was more than anyone else in the country responsible for placing this scheme on the Statute book He was a man of genius, and without him even the great genius of Lloyd George could not, I venture to assert, have fashioned and forged his mighty measure The first medical insurance commissioner, Smith Whitaker was roundly abused throughout the profession for going over to the "camp of the enemy," as they described it, and giving up his post as medical secretary of the BMA Why he should be thus abused I have never been able to discover He was the man of all others most fitted to contribute to the administration of national health insurance the point of view of the medical profession He went on to the commission with that object and that object only in view, and the medical profession owes him tribute

Why did the medical profession of that day view with such hostility the revolution which was brought about in the conditions of medical practice ? Of course it was a revolution, and I think it was the fear that the old bad cheap-and-nasty club practice was to be imposed on the nation, and that the standard of medical treatment was to be lowered that worried the medical men Obviously the money difficulty caused much unrest , for, when the capitation fee was fixed at a figure which was regarded as reasonable by the profession the signing-up of the new contracts ready for the start of the scheme in 1913 went ahead quite gaily In the thirty years which have gone by a new generation of doctors have grown up who know nothing of the days before National Health Insurance existed , they must often wonder what all the fuss was about and why it should have been so generally accepted that a doctor will give less valuable service because he is paid by a capitation fee instead of by means of a fee for each attendance

What has National Health Insurance achieved ? As a scheme for the cure and prevention of sickness, which it was, it has on the whole been a conspicuous success It has been accepted as such over and over again by the representative body of those engaged in practising it, and there is no doubt at all that as an organised scheme of medical service for the working population it has justified itself in its operation But who will deny that in the field of prevention the expenditure of so many millions of money might have been made to better advantage ? The trend of medicine towards prevention rather than cure is slow, painfully slow But at long last we seem to be on the brink of great changes and experience gained in the NHI scheme, with all its defects, will surely be of great value in the days ahead when effect will undoubtedly be given to the recommendations now being framed by the BMA Planning Commission That, of course, is not to say that the recommendations will be adopted either in their entirety or with their limitations, but we are on the eve of the establishment of some form of unified national medical service That is without doubt

Doctors and approved societies, starting in 1912 from the unpromising datum line of mutual distrust, have progressed to the position that they trust and respect one another, and really get along quite nicely I am confirmed in this view not only from personal observation on the London medical service subcommittee (where I as chairman am supported—or, better still, guided—by three representatives of the profession on one side and three of the societies on the other) but also because formal complaints about certification have almost vanished from the scene And that can only have come about because there has been a better understanding and many informal settlements—often promoted if London is any guide, by the good offices of the clerk to the insurance committee These committees were created to reconcile the doctors to some measure of administrative control by the approved societies Of pure and unadulterated control by the societies, they would have none But in an insurance committee, where the doctor could sit cheek by jowl with the society's secretary, a happy compromise was found And whatever kind of rabbit comes out of Beveridge's hat this autumn, some seasoning of this kind will have to be found when the rabbit is served up on the table Sir William is studying the whole problem of social insurance administration Arising out of his survey one may anticipate that medical benefit will be neatly severed from the administration of the NHI cash benefits And in the process of reconstructing something better there should be no place for the sweat and blood of 1912

In thirty years the medical profession have learned the value of organisation in treating the mass of the morphia and warmth to abolish the anoxia and restore the nervous centres and therefore the muscles, to a normal condition Where there has been definite loss from the body of the oxygen carrying red blood corpuscles, restoration of the circulating blood volume, even with the administration of oxygen, is not enough, for serum will not transport oxygen red blood cells—whole blood—must be given Three years of war have not yet solved the primary problem why the nervous centres *fail* Henderson, perhaps not unnaturally, strongly favours the view that alterations in the respiratory gases—carbon dioxide and oxygen—are responsible The evidence for this view is strong but by no means overwhelming, and extensive investigations are being carried out on this point both here and in the United States Fortunately for the patient, practice is in advance of theory

WHAT'S WHAT IN EMERGENCY

NOWHERE to go nothing to eat and nothing to do To meet the lot of those rendered homeless by enemy action, central health departments have been at pains to offer instruction and advice the Department of Health for Scotland has now codified some thirty circulars about information centres in a little pamphlet[1] issued at a modest price The first part deals with publicity, the third with the central index which is a necessary part of the machinery The second part is human it tells all about information centres—selection of premises their equipment and adaptation staffing and arrangements for setting them up The centre should be in a school public library, hall or other suitable building not part of the municipal offices Plenty of seats, a canteen for light refreshments, tables to write at, simple first aid appliances and a telephone help to give a confident club like air to the place , official needs are served by large notice boards, armlets card indexes and of course supplies of the right forms and good blackout and window protection Voluntary workers take charge—anything from four to twenty of them according to the size of the centre—under general supervision of a director who will guide inquirers to the departmental officers attending to give expert advice and assistance When the need arises, the decision to open an information centre must be reached quickly , to secure this the department insists that responsibility for taking the decision should be delegated in advance to a senior official The pamphlet will be a pillow book to this delegate and all his satellites As the Secretary of State remarks in a foreword, much can be done to allay distress by making prompt and accurate advice available and by using experience of past raids to meet present difficulties When the bottom suddenly drops out of people's lives such a centre steadies them and helps to restore their shaken sense of security

NEW BROOM IN THE GUT

THE great reduction of coliform bacteria in the fæces of mice given sulphaguanidine by mouth and the beneficial action of this drug in bacillary dysentery[2] raised hopes in the surgeon that it would be useful in intestinal surgery Much of the secondary infection that complicates colostomy and bowel resection arises from leakage of *Bacillus coli* into the peritoneal cavity or around the abdominal wound, and intestinal surgery would be safer and easier if this organism could be eliminated from the bowel before and after operation However, sulphaguanidine proved disappointing, for reduction of the coliform bacteria was accomplished irregularly and only in cases where there was no intestinal ulceration[3] Moreover, experiment showed that intestinal obstruction might allow undesirably great absorption of the drug from the small gut, which with impaired renal funct would result in high blood levels and a greater risk toxic reactions But the search for the ideal intesti antiseptic—a substance with high antibacterial pow low toxicity and poor absorbability—continu Succinyl sulphathiazole [2-(*p* succinyl aminobenze sulphonamido) thiazole or sulphasuxidine] one of series of dicarboxylic acid derivatives of various sulph amides prepared in the research laboratories of Sharp Dohme goes a long way to satisfying these requiremen This drug is effective against *B coli* and the dysent group but not apparently against the salmonellas, *proteus* or the fæcal streptococcus When the drug given by mouth to patients, the stools become soft odourless, flatus is greatly diminished, and the *B* content is reduced from many millions to 100-1 per gramme of wet fæces, a remarkable achieveme Ulcerative lesions in the bowel, active diarrhœa severe constipation retard but do not destroy its ciency Part of the drug appears in the fæces sulphathiazole, which Hawking[5] has shown to be m active than sulphaguanidine in suppressing the f flora There is also evidence that considerable amou of the drug are excreted in the bile,[6] and this may b step towards the effective chemotherapy of typhoid paratyphoid Large dosage—0 25 g per kg of bo weight daily in 5–6 doses—is recommended , only ab 5% of the drug is absorbed, giving blood concentrati usually under 1 mg per 100 c cm so that there is prac ally no risk of toxic reactions Firor, who has used drug in over 120 surgical patients, gives 4 hourly do for 5–7 days before operation, avoiding cathartics especially mineral oils, and continues treatment for days postoperatively when anastomoses have be performed Medically, besides bacillary dysentery, drug is recommended for the relief of abdominal diste sion in typhoid and in conditions with an associated ile

INFECTION FROM THE DROPPER

THE use of vasoconstrictors like ephedrine for treatment of colds and nasal catarrh has become popu in recent years By contracting the congested muc membranes they certainly give a sense of relief , whet they help to abort or cure a cold is another matt Indeed it has been suggested that their use increases risk of secondary infection by allowing bacterial pat gens easier access to the adjacent sinuses These seco ary bacterial invaders may already be present in nasal passages, but the risk of their being introdu from an outside source has just been demonstrated Gompertz and Michael[7] The ephedrine or some analo is usually dispensed in dropper bottles, and may or n not contain a small amount of an antiseptic or aroma oil which, in the presence of any nutrient material, little or no bactericidal action If therefore the drop is repeatedly inserted into the nostrils, it is liable to t back with it mucus, pus and debris which could supp the growth of any hardy pathogen contaminating dropper In fact, Gompertz and Michael have found t 19 samples of nose drops with droppers that had be used for at least one week were all contaminat *Staphylococcus aureus* being isolated from 16 of the By contrast, 6 samples from partly used bottles contain similar solutions without antiseptic and, more importa without droppers were all sterile The moral seems be that if you must use a dropper-bottle, buy a very sm one, allow no one else to use it and throw it away wh you've finished with it Alternatively, get your no drops in a dropperless bottle , pour out a little of solution into another container and be sure to rinse boil the dropper afterwards

Sweden was alone, among countries with sterilisation laws, in not having control of voluntary sterilisation They were supported in this opinion by the medical and social councils and various medical societies The working of the 1934 sterilisation law had shown that guarantees against sterilisation of such responsible persons on inadequate grounds were needed far more than measures to protect those incompetent to give consent In 1941 a new law was passed, defining the conditions for which sterilisation could be performed with the consent of the patient, and providing for the operation to be done without consent in those incompetent to give it On eugenic grounds, a patient may be sterilised to prevent inheritance of physical defect or other serious disability , and on medical grounds when there is risk that owing to illness, physical defect or weakness pregnancy might cause serious harm to life or to physical or mental health On social grounds patients may be sterilised who seem on account of mental defect or disease or other psychic abnormality to be incapable of caring for children Those guilty of antisocial behaviour can also be sterilised, and this covers chronic alcoholics and criminals, regardless of their mental state In other Scandinavian countries sterilisation of sexual *criminals implies castration, but this is not yet the case* in Sweden, though proposals for such an extension of the law are under consideration

Under the Swedish law of 1941 sterilisation may only be undertaken with the consent of the medical council, unless there are urgent medical grounds for it Thus a woman able to give consent may be sterilised without official sanction if, owing to physical defect or disease, pregnancy may seriously endanger life or health, provided the doctor performing the operation and another doctor certify in writing that the indications are present The written certificate may be omitted if delay would endanger life—for example where a surgeon is terminating pregnancy by an emergency operation on account of illness or defect, and wishes at the same time to prevent further pregnancies The woman, or if that is impossible a near relative must have given consent Women must be sterilised in a hospital or some institution of similar standing , there is no similar regulation about men, but the operation must be undertaken by a qualified practitioner There is no appeal from the decision of the medical council except on a negative verdict, and permission to sterilise becomes invalid if the operation is not carried out within a year of application Those eligible to apply for sterilisation are the patient , the guardian of those under age , the husband or wife , the poor-law authority for those under poor-law care , the child-welfare authority for children under their care , the doctor in charge, or the superintendent in the case of hospital outpatients or inpatients , various doctors employed by the state Any doctor who learns, from the local authority or otherwise, of a case requiring sterilisation is required to see that the application is made and the operation carried out Doctors at mental hospitals are instructed to apply for permission to sterilise all patients for whom the operation is thought desirable before discharging them or boarding them out Where the operation is not carried out the reasons must be stated on the case-sheet In the case of mental patients not in institutions, state practitioners on learning of a case are required to apply for sterilisation, if it is needed, and see that it is carried out

It is thought that sterilisation of mental defectives cannot be effectively extended until there is legislation compelling all educable mentally defective children to attend special schools This would ensure that no mental defective would reach adult life unsterilised, and that no high-grade defectives—particularly women—would be discharged from institutions until the operation had been performed

---

The Ministry of Food has arranged for an inquiry into the nutritive value of the meals served in the 1500 British Restaurants Analyses of the meals will be specially directed towards ascertaining their vitamin and mineral content, and how much of this is lost or destroyed by the different methods of cooking employed The inquiry is to be of a searching character and will cover a long period of time

In England Now

A Running Commentary by Peripatetic Correspondents

Ruth Benedict's book " Race and Racism " (London Routledge) left two dominant impressions on my mind that it is the sanest book I have read for a long while , and that, since every educated person ought to read it, it is a pity it costs 7*s* 6*d* I overcame a little prejudice against the word " racism " in the belief that it was probably employed deliberately to signify the false teachings of the Aryan or Nordic myth , this belief was, however, dispelled by finding on p 136 racism used with exactly the same connotation as racialism on p 137 It is a human weakness that we approve a work which says in better form what we ourselves have thought and have even tried to say It was admittedly this weakness which prompted me to approve the historical approximation of the findings of Gobineau in the early 1850's with the conclusions of Charles Darwin in 1859 , for Benedict points out how much new force Gobineau's thesis gained by Darwin's teaching of the " survival of the fittest " But this slogan, which has produced so much evil in the world today, was due to Herbert Spencer and *not* to Charles Darwin Spencer coined this phrase as Tennyson coined " Nature red in tooth and claw " but Darwin is blamed for all their implications If we might take a new slogan from Ruth Benedict we might select that in which she sums up the results to be learned from intelligence tests " Individual differences will still remain in all races, but the results indicate that any programme which proposes to increase human achievement will attain its ends by providing adequate and continued opportunity for any individual without regard to race or colour " My one criticism is concerned with this statement about primitive man " With the simplest savage equipment—no boats, no agriculture, no breeding of animals—he reached Australia and maintained himself in its punishing deserts " Man reached Australia in a primitive cultural stage, but if he came by land a vast zoological dilemma remains to be solved and the dingo has some claim to being regarded as a domestic animal As an antidote to the stupid perversions of so-called anthropological science that have provided a stimulus for evil-doing in our times, no better book than this has been written It is clear, simple and accurate Every person who claims to be educated and to be in a position to discuss the implications and origins of modern happenings should read it—and it is understandable by all

* * *

Still in Iceland, you see, but I have now left my centrally heated flat and the flesh-pots of the town and gone into residence in half of a Nissen hut on the seashore I have no batman, so I do my own laundry (after a style) and mending, sweep out the hut, grope for coke in the remains of a dump (luckily just outside my door) and for bits of wood and paper wherever possible, lay the coke-stove fire (for it is still mighty cold in spite of sunshine), clear away and dump the ashes polish my buttons, and black my shoes—all in my " off " time To add to my difficulties, everything becomes covered and impregnated with lava dust We get lava-dust storms equivalent to the dust storms of Libya I have seen mountains for miles completely blotted out from view, and sometimes dust storms blow out to sea and interfere with air patrols The upper part of the beach here consists of rounded pebbles and chunks of lava, smooth and water-worn it is covered with the golden flowers of silverweed and with some lovely low-lying pink and blue flowers whose name I know not Lower down the beach the flat layers of lava emerge, strewn with lava blocks covered with minute periwinkle shells Eider and long-tailed ducks, redshanks, turnstones, ringed plover, sandpipers oyster-catchers and Arctic terns abound along the shore, and white wagtails, whimbrels, snipe, mallard, and Greenland wheatears nest round the camp , and one small ditch harbours three red-necked phalaropes In the last-named species the usual physiological division of labour among birds is reversed the hens are more brightly coloured than the cocks , the hens amorously pursue the *cocks , the cocks* sit on the eggs and feed the young Not much room for polygamy here, but possibly for polyandry

A fortnight ago I visited a lake, in the interior with numerous boiling springs along its edge which give off , insured population. This experience should enable them to cooperate with the administrators in producing a comprehensive and well-ordered scheme for placing the health of the people on a sound and enduring basis. The first consideration, as Disraeli said, is the health of the people.

PLANS FOR THE CHILD

At the annual general meeting of the maternity and child welfare group of the Society of Medical Officers of Health on July 3, presided over by Dr Virginia Saunders-Jacobs, the group committee presented an interim report on medical planning in which the place of maternity and child welfare work in its widest sense naturally ranked high. The report suggested that education of the public should begin with the organised teaching of parentcraft in schools and elsewhere throughout adolescence. A complete maternity and child welfare service, with ancillary services would be available for all, as part of a national salaried general medical service organised as some form of regional scheme, with the health centre as the local unit. While this is being established there should be no interruption of the progress in maternity and child welfare now being accomplished, the preventive services would develop the principle of regular and adequate medical supervision of the child up to school-leaving age until a national service was ready. Prevention and treatment of illness in children would be in the hands only of doctors with postgraduate experience of the subject. The maternity and child welfare services would be amalgamated so that one service covered the child from birth to school-leaving age.

Unlike Dr Mathilda F Menzies,[1] the committee had no doubts about the advantages of hospital over domiciliary confinement, and urged that sufficient hospital beds should be provided for all women who need or desire them. Maternity hospitals, they felt, should be separate units but attached to general hospitals. Obstetric care and confinement of the mother apart from general supervision would in all cases be carried out by a specialist obstetric service, based on the maternity hospital. There would seem to be no recognised place for the midwife in such a plan unless she is to be responsible for the "general supervision", and it is arguable that a purely specialist service, besides being expensive would inspire in the mother a belief that the bearing of children was a highly dangerous affair. (It is well to recall Uncle Toby's silencer to Dr Slop: "I wish you had seen what prodigious armies we had in Flanders.") The report also pointed out that hospital beds for women who need investigation during pregnancy are scarce at present. A minimum of 10 beds per 1000 births in an area it was suggested, are needed for antenatal purposes, in addition to hostel accommodation for expectant mothers which should be attached to maternity hospitals, especially in rural districts. Hostels and short-period residential nurseries could also be provided for the care of the children while the mother was lying-in. In discussing the report Dr Violet Russell noted that it proposed a complete service, operating through health centres, to cover preventive and curative medicine for children of all ages. It was agreed that the general practitioner would take an increasing part in this service, but it was felt that neither he nor the antenatal clinic officer of today was qualified to undertake both prevention and treatment of disease in children. The University of Aberdeen has provided as part of the curriculum for medical students courses of instruction and practical work in child welfare, under the direction of the regional medical officer for maternity and child welfare. Other medical schools may follow suit. Certainly the coming generation of doctors will be expecting to take a fuller part in social medicine, as the founding of the new chair at Oxford indicates. Maternity work, it was felt, would and should develop as a separate service from child welfare, which ought to be more closely linked with the school medical service. This would undoubtedly be sound policy, the gap between the last inspection at the infant welfare clinic and the first inspection by the school doctor has been a grief to public health workers long enough. Dr Saunders Russell pictured the health centre of the future as being staffed by a group of doctors two or three of whom would have special training and interest in the prevention and cure of disease in children.

STERILISATION LAWS IN SWEDEN

Sterilisation is controlled by law in the Scandinavian countries. In Denmark as early as 1920 Prof Christian Keller urged the government to legalise sterilisation of any abnormal person if he, or those responsible for him, applied for it and the first sterilisation law was passed in 1929. In 1935 this was replaced by a new law under which even psychically normal people could not be sterilised except with the consent of the Minister of Justice, he can authorise the operation, on the advice of medico-legal authorities, if there is risk of transmission of hereditary disease. In Norway a law passed in 1934 gives to the medical director only the power to consent to operation where the application is made on sufficient grounds. In Finland, in 1921, the authorities finding that defectives were often sterilised before discharge from institutions took steps to legalise the practice and under the law of 1935 anyone capable of judgment may be sterilised with the consent of the medical council if there is risk of defective offspring. It can also grant permission in the case of those who owing to some psychical abnormality, might commit a sexual crime, when the treatment implied is castration. Prof Alfred Petrén[1] tells how, as inspector of the Swedish board for mental disease, and a member of parliament, he helped to establish a committee of experts in 1929 who studied the problem and advised that sterilisation should only be practised on those capable of understanding what was being done and of giving their consent. Those who lack this degree of capacity, they argued, are nearly always segregated in institutions. However, the need for institutional care does not necessarily go hand in hand with mental capacity. Thus high-grade mental defectives with uncontrolled sexual habits may need segregation whether they are sterilised or not, whereas many low grade easy-tempered defectives who can well be managed at home need sterilisation because they may be persuaded into sexual promiscuity though they have no particular inclination to it. Many Swedish doctors urged that sterilisation should be permitted on social and eugenic grounds, though not on social grounds alone, and the medical council was of the opinion that the chronically insane and mentally defective should be sterilised because they were incapable of looking after children if they had them. After much debate, the proposals came to nothing, but in 1933 Professor Petrén opened the question again, and new proposals, drawn up by Prof R Bergendal, professor of criminal law at Lund University, came under consideration. He took the view that responsible defectives could be voluntarily sterilised without further legislation provided there were adequate criminal, political, humanitarian, social or eugenic reasons for the operation. It was generally felt, however, that such voluntary sterilisation could not be left quite unregulated in this way. In 1934 a law was passed regulating the sterilisation of mental defectives who were too low-grade to give valid consent to the operation, it was provisionally agreed that surgeons who were asked to sterilise such patients should send reports on the cases to the medical council, which would make the final decision, a patient could be sterilised without permission of the medical council if two qualified practitioners deemed it advisable, and if the patient or those responsible for him gave consent in writing. In such a case a full report had to be made to the council. Meanwhile proposals for regulating the voluntary sterilisation of those defectives competent to give consent—to whom the law did not apply—were under consideration, and as an interim measure surgeons were required to send a full report to the medical council of all such cases which they undertook. This was to give the council some idea of how often, and on what grounds, those operations were being done.

The Swedish population commission, which later reported on the results of the 1934 sterilisation law, urged that the sterilisation of people capable of making a judgment (normal people as well as defectives) should be regulated, and pointed out that

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS M P

WE were occupied last week in debating production and (in secret) shipping. Behind both of these debates looms the question of food-supply the first necessity of production and its relation to shipping space available for munitions of war or the transport of armed forces overseas. Lord Woolton informed the Upper House that we are spending £127 000 000 a year in subsidising foodstuffs an expenditure which has largely contributed to stabilising the cost of living. As a result not only are prices kept within bounds but because of the control and direction exercised foods are in very good supply. The question the nation will have to ask itself. as the intensity of the war effort increases is how far we can limit our imports of food and how far we can increase our home-grown food-supplies

Reserves of food in this country are good · some foods such as tea we are even exporting. The milk situation is good and the extension of the milk-in-schools scheme and of the supply of school dinners go a long way to meet the obligation of child nutrition. All schools supplying meals not only those under the local education authority are to have extra rations. The rise in liquid milk consumption during the war deserves more attention than it has received. In 1941 there were 202 million gallons more milk consumed than in 1939 an increase of nearly 25%. As milk rationing has been suspended during the summer no doubt the figures are now still higher. Potatoes are so abundant that there were complaints in the House of waste of last year's supplies (which had been held as reserve against the possible shortage before this year s crop matures) one member suggesting shooting those responsible and another shooting those who would not eat them. A brisk but brief potato war on the Conservative back benches (Casualties nil) What the effect of the new restrictions on poultry foods will be on the egg supply next year is problematic. It may have very little effect if small poultry keepers learn to use kitchen waste more effectively. Fruit and green vegetables are in ample production but perhaps need better distribution. The country is habituated to the meat ration and doing so well on it that one wonders if a great deal of prewar meat consumption was not just waste. The grain harvest is yet to be got in but prospects are good (and if nothing worse happens to our bread than the addition of a little rye, as the Minister of Agriculture proposes we shall have little of which to complain

If 1942 is to be the year of the Second Front then our home population seem assured of good food-supplies. One trusts that Major Lloyd George, who only recently left the Food Ministry to become Minister of Fuel and Power and wrestle with our tough fuel problems, will be as successful in his new sphere as he was in his old. In the spheres of armament production of all kinds of food and of fuel we are facing problems of adaptation of planning and of careful contriving—we are not facing problems of dearth and insufficiency of materials. If we tighten our belts it is to create reserves for the still bigger efforts that lie ahead of us

FROM THE PRESS GALLERY

Education after the War

EDUCATION is important to every nation but most of all to a free country for, as Earl DE LA WARR pointed out in the debate in the Lords on July 15 of all forms of government the most dangerous is an uneducated democracy. Lord SAMUEL in his wise opening speech pled for the extension of education in length breadth and depth. We should take in children under five and give part-time education to our young people over fourteen. He pointed out how much physical training school medical services the distribution of milk and the provision of meals have done for the health of the nation as a whole. Lord NATHAN said we must prepare now to cope with what would be an urgent post-armistice problem. After the cease-fire the nation would be in a ferment of confused emotions families would be reassembling and in urban areas many schools had been destroyed. Above all we should provide educational rehabilitation for the young people who had had to postpone their higher education on account of the war. Army life impaired the habit of intellectual application and it would not be easy for them to return to their studies. He thought they should not be demobilised at once but should continue on service pay and be seconded from their units for refresher courses. Of their natural quality there was no doubt , it was up to us to give them the education that would burnish that quality into competence. Lord SOULBURY welcomed the extension of education for it would give us an opportunity to fill two important gaps in our health service—the under-fives and the fourteen-to-eighteens. The Ministry of Health has power to set up infant-welfare centres but parents have not always taken advantage of these facilities. Education authorities are only responsible for the medical inspection of children attending school. Before the war there were about a million and a half children in the 2–5 age-group. Of these only a seventh—mostly over 4—attended nursery schools and were eligible for the medical care provided by the education authorities. War-time nurseries had improved the situation but they were necessarily an improvisation and as such were—he thought probably rightly—administered by the maternity and child-welfare authorities" But he was not sure this arrangement was a suitable permanent solution. Later he would like to see the care and training of these children given over to the educational authorities. who would assume responsibility for the medical inspection of all children over 2 whether they were attending school or not. Before the war many school entrants were found to have defects which should have been discovered and treated earlier. Lord SELBORNE in his reply showed that the Government is mindful of these breaches in our health defences, for he said that a potent argument in favour of part-time compulsory education for adolescents was that it would enable us to supervise the physical health of young men and women up to 19

QUESTION TIME

Workmen's Compensation Payments

Replying to a question Mr H MORRISON said I have recently had under consideration representations made by the Trade Union Congress general council in regard to benefits, but as a Government committee are undertaking a comprehensive survey of the social insurance and allied services including workmen s compensation, I have come to the conclusion that legislation proposing substantial amendments of the existing scheme could not usefully be considered pending the report of that committee which is expected within the next few months. Payments under the act in disablement cases were substantially increased two years ago by the Workmen s Compensation (Supplementary Allowances) Act 1940

Army Doctors and Civilian Cases

Mr D SANDYS informed Mr I C HANNAH that Army medical officers may where necessary assist civilian doctors so long as this does not interfere with their military duties. Many medical officers have been granted temporary release from the Army to meet civilian needs —Dr E SUMMERSKILL Does this apply only to specialists ?—Mr SANDYS It does not

Appointment of Refugee Doctor

Sir HENRY MORRIS-JONES asked the Minister of Health whether sanction had yet been given by his department to an application made six weeks ago on behalf of a distinguished Czechoslovakian doctor of unimpeachable references who was a recognised authority on rheumatism to take up an appointment offered him by a group of collieries in the Midlands to coöperate with their own medical officers in a clinic for the prevention and treatment of rheumatism and allied disease amongst miners —Mr E BROWN replied. The colliery clinic has been approved as an institution at which a foreign-qualified doctor may be employed under the Medical Register (Temporary Registration) Order. My approval was given as soon as certain questions of principle regarding the employment of foreign doctors in this new field of industrial medicine had been settled in consultation with the Government departments concerned and the Central Medical War Committee

Refugee Dentists

Mr T E. HARVEY asked the Minister whether his attention had been called to the increasing need for qualified dentists sulphur-impregnated fumes Over one spring is a wooden hut, divided into two compartments, probably male and female, to provide steam baths locally esteemed (no pun intended) in the treatment of skin and chest diseases Thoroughly sweaty and choked with sulphur fumes one dashes into the icy lake for a swim and then runs to a dressing-room and gymnasium belonging to a large modern high-school, which is used in summer (April to September) as a hostel for visitors (there is no schooling in summer in Iceland—most of the older children go to the country to help in farmwork) This year the sleeping accommodation is occupied by mothers and small children evacuated from Reykjavik, but visitors can still get meals at the hostel, which is centrally heated by steam collected from one of the geysers by the lakeside A supply of hot water is provided by bringing cold water, from a mountain a mile away, in a pipe to the geyser, where it circulates in an enormous submerged radiator, whence it is conveyed piping hot to the hostel (The water from the geyser itself cannot be used because of the sulphur in it) A hut built over another hot spring is a laundry , another a forcing-house for tomatoes and cucumbers What look like children's sand-castles at the lakeside are cones of hot sand used for baking bread The loaf is placed in a hermetically sealed tin, wrapped in a sack, and buried for twenty-four hours Another spring, with a pleasantly warm temperature of about 80° F , is a semi-sacred spot, being where recalcitrant heathen were chucked in for immersion baptism at the forcible "conversion" of Iceland to Christianity centuries ago They had refused baptism elsewhere on the plea that the water was too cold Alongside are several small boulders on which was washed and prepared for burial the body of a famous assassinated Icelandic bishop The site measures only a few square yards and is enclosed by a small turf wall There is no inscription to enlighten the visitor In England one would expect, in such a place, paths, railings, notices, photographs on postcards, ice-cream stalls, vendors of descriptive pamphlets I prefer the Icelandic way

After luncheon, consisting of soup, a mutton broth containing *points d'asperge*, followed by stuffed meat served with jam and potatoes and by stewed rhubarb and lashings of cream and rounded off by excellent coffee with yet more cream, we sunbathed on the mountainside among profuse birch-scrub, the haunt of innumerable meadow-pipits, redwings, snipe, and a few Greenland redpolls Higher up the mountain, above the birch-scrub the ground was covered with many different kinds of saxifrages and other rock-plants , orchises , butterworts (with their greasy fly-catching leaves) , heaths of different sorts, including one with a solitary-white bell at the end of a four-inch stem , bilberries , and wineberries, like miniature crab-apples At seven o'clock we returned to the hostel for supper and found several tables set out in a long line down the centre of the hall and covered with hors d'œuvres Everybody—guests, evacuated mothers and children old enough—took a plate and a fork and helped himself to whatever took his fancy among slabs of cheese, smoked saithe (a sort of salmon), smoked herring, herring soused in wine-sauce, cucumber, pickles, potato salad, Russian salad, Icelandic salad (covered with a beetroot-pink sauce), white bread rye bread, ewe-milk butter and so on This was followed by a hot dish of white fish, potatoes and rice, and by a sweet and coffee Half an hour later we went "back to base" in a 'bus—a 50-mile run over a dizzy mountain-pass with splendid views of Mt Hekla, several glaciers, and the Western Isles (named after the original Irish settlers found already there by the first Norwegian settlers)

* * *

Fancying myself at dental gases, I conveyed tactfully to the dentist of our internment camp that I intended to take an active part in future extractions of those unfortunate enough to be my patients The dentist, no doubt reminding himself that there was a war on, agreed with a charm and alacrity that did him and his inhibitions great credit , and a couple of mornings later found me hurrying up the stairs of the erstwhile boarding-house that now masquerades as an emergency clinic The dentist, through either modesty or inability to sway the great ones who control our destiny, inhabits an eyrie on the top floor which in prewar days probably served as a box-room , and as I force myself in at the door I cannot help wondering how it will settle down to that hu occupation again after the bloody and exciting con it has witnessed in the last two years These wh reflections, however, are lost in the difficulties of clea a passage through a vast throng But on achieving Mecca, the dental chair, I realise that while six p may constitute a record in dental assistance, it is their compression in a room 8 ft by 8 ft that give massed effect First—and indispensable—is the de himself , then there are two foreign dentists who him regularly and can hardly be banished when unknown quantity—myself—may be about to kill of their compatriots They both bow stiffly fro waist, imperilling a tray of forceps on the window The other two occupants of the room are the den receptionist-nurse, who is keeping an eye on his inte and the outpatient sister who has just popped up downstairs to keep an eye on mine

Zero hour coincides with my arrival, and sister flatten ourselves in corners as the first barrage of effic is put over Glassy eyed, I watch X and Y, the foreign exponents of the art, darting about, turnin bunsen burners and flaming things in lakes of s From the wash basin, where he is scrubbing up w fine disregard of the soap ration, the dentist speak a manual of hygiene Impressed, sister and I view other over their milling heads and being an easy to propaganda, I remain awed until a cynical gleam i eye punctures my credulity Would the devote hygiene so often meet head on if this were no routine ? Did not Y make an involuntary moveme pick up a fallen swab, before kicking it, with an conscious rectitude, into a corner ? Does not X vie gauge on the steriliser with undue anxiety ? Fr they and their English overlord go into a huddle nea wash-basin, and sister and I listen to a serious and voiced discussion on procedure The gag, nearly b to pieces, is transferred to a kidney dish "Better it," advises the dentist in crisp tones, and watches simple pride as Y holds it under the hot tap Mean X proceeds to dish up the contents of the steriliser, uneasy about the drum of swabs (the presence of w is never explained) puts them to air on the window l with the lid open Half of them are removed by sea before he can get the window up again A happy d sion is caused by the entry of the patient The do locked and the stage set for the final drama I inflat bag, making encouraging noises, and try to listen t patient's respirations, but his breathing—if he is breathing—is lost in the roar of the steriliser which turned full on again, perhaps as a symbol of his agitation The forceps gleam, and we sway rhythm to avoid the hail of teeth that patter on the floor three four five That's the lot The ist straightens himself We all smile at each c conscious that we have acquitted ourselves well

At this moment the patient begins to scream lo and is only induced to stop and open his eyes by the ministrations of sister with a water-soaked swab smile fades from the faces of the two aliens, who r me with liquid, accusing eyes till I am vindicated b patient Rising, he shakes me warmly by the hand says "I 'ave never 'ad one such nice time before— I inquire fretfully why he screamed if he enjoyed hi so much "Always do I do this," he replies, sm brightly "Yes Cheerio !" He shoulders his out of the room, and international confidence is rest We wait for the next patient He does not come He never comes, having faded away on the first not his fellow countryman's halloo

* * *

When one deals with flying personnel one accep inevitable the multiple forms provided to keep records of their health These papers travel abou world from station to station making plenty of cle work It is apparently not done, in the Services, su to send only the forms one must add a formic covering note explaining one's reason for sen them for example "Retention" or "Re-forwardi I have often puzzled as to why copies of these docum come to anchor where they do, and I can sympat with the unfortunate who recently sent us a cove chit which read "Reason for forwarding documen Not Known"

TOTAL *versus* SUBTOTAL HYSTERECTOMY

SIR,—Your leader of July 11 on hysterectomy ignores he most essential point—the function of the cervix. know of no intrapelvic pathological condition which will produce carcinoma of the cervix, so that total hysterectomy should be performed only on those cases where carcinoma is evident or strongly suspected. To emove the cervix for leucorrhœa or any other symptom of endocervicitis is to remove the nose because of rhinorrhœa. This analogy goes deeper than is apparent, since to remove the nose completely would be to abolish the sense of smell. To ablate the cervix is to destroy its function, a particularly important one in the life of a woman, of lubricating the vagina during coitus, and of producing the secretions which materialise the female orgasm. To remove the cervix is to end the sexual life of the woman. In many cases this is a greater tragedy than a cervical carcinoma. I once had a colleague who performed total hysterectomies as a routine, and to review his cases over a number of years was to meet many cases of marital unhappiness and personal misery. Too often I had to listen to the comment: "I wish I were dead, doctor." Surgical practice has too long tended to overlook happiness in its search to restore health.

Bridgwater M. P. REDDINGTON.

SIR,—Your leader describes the attempt made by McKinnon and Counseller to assess the relative advantages of total and subtotal hysterectomy from the case records of 2684 operations performed at the Mayo Clinic. In my opinion the figures in the original article do not bear out the interpretation put upon them. Your statement that "this is a formidable array of material, large enough to reduce the statistical error to a minimum" contains the unwarranted assumption that the value of an investigation is in direct proportion to the size of sample of the community tested, independent of bias. Even in a series of 2684 hysterectomies, there are many upsetting factors—such as age, parity, weight, skill of the surgeon, anæsthetic, and especially technical difficulty during the operation—any or all of which may have heavily increased the bias against one or other type of operation. The subdivision of the whole series into two grades, good and bad operative risks, does not eliminate possible bias, especially as the criteria for including cases in one or the other grade are not given. The statement "in the group of good surgical material the type of operation was the only known variable" is therefore open to criticism.

The conclusion has been reached that "the elimination of the cervix as a source of subsequent trouble and the lower immediate mortality-rate of the total operation far outweigh the risks of any complication that may arise after total hysterectomy." This is based on the evidence of the two following tables:—

TABLE I—DIFFERENCE IN MORTALITY RATES: ENTIRE GROUP

Procedure	Cases	Hospital deaths	Per cent.
Total hysterectomy	1920	15	0.78
Subtotal hysterectomy	764	8	1.04

TABLE II—DIFFERENCE IN MORTALITY RATES: CASES OF LEAST RISK

Procedure	Cases	Hospital deaths	Per cent
Total hysterectomy	1034	2	0.18
Subtotal hysterectomy	463	4	0.86

During the preparation of the second table 1187 cases have been discarded because they do not fit into the group of "cases of least risk." When the mortality figures for these 1187 cases—presumably of "greater risk"—are worked out, as can be done after subtracting the relevant figures in tables I and II, it is seen that the percentage death-rate is higher following total than subtotal hysterectomy.

TABLE III—DIFFERENCE IN MORTALITY RATES: CASES OF GREATER RISK

Procedure	Cases	Hospital deaths	Per cent
Total hysterectomy	886	13	1.47
Subtotal hysterectomy	301	4	1.33

Thus, by using the same methods as the authors', there is in nearly half the total cases a higher mortality associated with the total operation than with the lesser procedure. The original figures, therefore, might almost as well have been used to show that the total operation was more dangerous than the subtotal operation.

In conclusion, however, it must be emphasised that the differences in the mortality-rates after total and subtotal hysterectomy in all three tables are not statistically significant. For example, in McKinnon and Counseller's first table, assuming an identical risk for each operation, the same or a greater difference in mortality-rate would be expected to occur by chance in at least 50 per cent. of similar samples. No conclusions as to the relative risks of the two operations can therefore be drawn from the figures available. It seems a pity that the blessing of THE LANCET should have been given to statistics of such questionable value.

Nuffield Department of Obstetrics and Gynæcology, Oxford. C. SCOTT RUSSELL.

EPIDEMIOLOGY OF JUVENILE RHEUMATISM

SIR,—In their interesting paper Dr. Morris and Mr. Titmuss write (p. 62): "The concept of a 'rheumatic stratum' (Miller 1926), excluding the well-to-do on the one hand and the very poor on the other, received no confirmation." This bald statement may be taken to imply that I have regarded the very poor as enjoying a freedom from the disease comparable to that of the well-to-do. Certainly I have never held nor intended to express such an opinion. The class incidence of juvenile rheumatism shows that it is peculiarly limited to the children of the poor, but that in them it is commoner in the upper and middle-class poor than in the very poor and destitute. This second point has been demonstrated by many investigators, and in particular it has been found that overcrowding is not a predominant factor in the mass-production of the disease. This, I note, has been shown once again by the present authors. This fact, as you, Sir, comment in your leader, is against the hypothesis that the disease is commonly transmitted from case to case by droplet infection, a view totally opposed to clinical tradition. Any infective disease powerfully influenced by environmental factors is bound to show some evidence compatible with the possibility of case-to-case transmission, but it is not easy to imagine stronger evidence against such a hypothesis than the absence of overcrowding as a paramount factor in its large-scale production.

Basingstoke. REGINALD MILLER.

THIRD GENERATION SYPHILIS

SIR,—Medicine never has been and probably never will be an exact science; but many of its phenomena observed over a long period give grounds for deductions which are legitimate, and probably even correct, without being susceptible of scientific proof. Among such phenomena I would venture to place the transmission of syphilis from an untreated congenital mother to her offspring. Mr. Johnston Abraham says that he has never been able to satisfy himself that the evidence adduced in support of this contention is scientific. In a paper based on my presidential address to the Medical Society for the Study of Venereal Diseases (1933), I gave records of 16 families with syphilis in three generations, and of 6 in which syphilis was probably and 7 in which it was possibly present in the third generation. I concluded that an untreated congenitally syphilitic mother might transmit florid congenital syphilis to her child even though her husband was healthy; but was careful to add that this conclusion was lacking in scientific proof. Since then several similar cases have come to my notice. Many problems connected with congenital syphilis await solution. Why, for example, in a mixture advocated ? Is the ferric chloride designed as an astringent, and if so where is it expected to act, or is it considered as a means of administering iron for anæmia, in which case the form is unsuitable and the dosage inadequate, or is it just a "tonic" ?

Tabella codeinæ composita (NWF, p 55), which is equivalent to 'Veganin,' contains gr ⅛ of codeine phosphate, which is an expensive substance How much does such a dose contribute to the total analgesic action and what would happen if it were omitted and the doses of aspirin and phenacetin were increased ?

These examples could be readily multiplied The criterion for inclusion of a drug in a prescription should be convincing positive evidence in its favour, and if none exists it should be excluded, a policy which might provide valuable information on the effectiveness (or otherwise) of doubtful drugs A distinction should be made wherever possible between the pharmacological and the psychological actions of drugs, and the number of drugs employed for both purposes, particularly the latter, should be reduced to a minimum, which has certainly not been reached in the NWF

I believe that the medical profession generally desires the elimination of the bottle-of-medicine habit Now, when restrictions of all kinds are willingly accepted by the public, is surely a suitable moment to reduce both the number and quantities of useless and doubtful drugs employed, in the interests of national economy and of clarity of therapeutic purpose The aim should be to set up a formulary containing a small number of drugs with clearly demonstrated actions, a few substances necessary for pharmaceutical reasons, and a few flavouring agents A few cheap, harmless substances should perhaps be included for psychotherapeutic purposes Such a formulary, desirable for peace as well as war, would help to establish more rational therapy

Middlesex Hospital Medical School C A KEELE

A GOOD GESTURE

SIR,—The China Medical Aid Committee appeals again to your readers to assist the National Red Cross Society of China In the past these appeals have been generously answered and now that China is our ally in name as well as in deed we put forward our appeal with even more confidence Three years ago nineteen medical men, who had been rescued from concentration camps in the south of France at the end of the Spanish War, were sent to help the Chinese Red Cross who had asked urgently for trained medical men as well as supplies This committee in cooperation with a Norwegian committee, financed and equipped these doctors and provided their maintenance so that the slender resources of the Chinese Red Cross should not be drawn upon The help of the Norwegian committee ceased in 1940 and we are the only body to which these doctors can look for support The doctors are working on various sectors of China's immense war front and two have been in the thick of the Changhsa battles All of them are doing invaluable medical and surgical work, and when they have time they organise first-aid training and teach hygiene to soldiers and civilians They lead the simplest and hardest of lives The following report, written by a young English doctor, is typical of work in south and central China

Our unit had charge of a hundred beds in the hospital, which was otherwise run by the military But the latter had neither the equipment nor the personnel to cope with the more serious cases, and these all came to us Most of the cases we had were very severe compound fractures and chest wounds that had survived the first week or so The abdominal and brain cases we saw little of, they had died before they could be brought to us But the fractures were bad enough They had come in carried on makeshift stretchers Exhausted with pain, their wounds covered with pus soaked dressings, dirt stained, and with appalling deformities through lack of proper splinting, they presented a sorry picture indeed

The Chinese Red Cross has a task so enormous to carry out that the aid we give seems ridiculously small but it is an earnest of our appreciation of the heroic resistance maintained by China and we appeal to you to continue that help for another year Donations should be sent to Dr E R C Hambly, Treharrock, Seer Green, Bucks

China Medical Aid Committee MILLAIS CULPIN, Chairman

REACTIONS TO THE REPORT

SIR —After hearing the report discussed at a meeting of medical men one is amazed at its good reception hitherto The sentiments stated to have inspired it are of the best, and the public press has in few cases looked further , but the measures proposed for translating these sentiments into action indicate that the authors attach no weight to the outlook of the political parties which will determine our future It is not clear that the public has anything to gain by accepting this report, or that its authors realised what the public needs and is likely to demand May I suggest an acid test by which this or any other report may be judged ? One outstanding feature of our present organisation is that independent competitive practice fails to provide a sufficient number of doctors in industrial areas As a result the people of those areas get only such attention, especially in winter, as can be given by a doctor almost too tired to sign certificates and utterly incapable of listening patiently to a series of medical histories We all know that from our own point of view this is an economic problem But from the public point of view it is a health problem for which neither general practitioners, nor clinics, nor health visitors have provided a solution Here then is the test does the Interim Report, or any other report provide a machinery which will bring to industrial areas the numbers of doctors needed ? There is little if anything in the report to suggest that the question has even been considered It seems to have been written by gentlemen wearing professional blinkers which have entirely shut out the public interest and forced them to concentrate on their own I have read various other reports but can truthfully say that what the BMA calls "the achievement of positive health" is given first place only in that drawn up by the Medical Practitioners Union

Sevenoaks GORDON WARD

PREPARATION OF INTRAVENOUS FLUIDS

SIR,—Your leader of June 27 and a letter by Mutch in your issue of July 4 draw attention to the advantages attending the medicinal use of charcoal Lees and Levvy (*Brit med J* 1940, i, 430) noted its use as an adsorber of pyrogenic substances, rendering unnecessary the distillation of water for preparing intravenous *infusion fluids in an emergency* We *emphasised* previously (*Pharmaceut J* 1941, 146, 258) the importance of adding charcoal to the solutions of the medicaments in distilled water as these frequently acquired pyrogenic properties during manufacture We have encountered certain disadvantages associated with the use of charcoal for this purpose, and as we have been consulted on several occasions regarding opalescence occurring in infusion fluids after the use of activated charcoal our experience may be helpful to those engaged in the preparation of infusion fluids

Activated charcoal is normally prepared by one of the following methods

(*a*) Direct method —Carbonisation then activation

(*b*) Briquette method —Material (anthracite, coal, wood, &c) briquetted under pressure then carbonised and activated

(*c*) Chemical method —Impregnation of material with a variety of substances, such as chlorides of zinc, calcium or magnesium, alkalis, alkali carbonates, sulphates or bisulphates, sulphuric and phosphoric acids, and carbonised at relatively low temperatures This carbon requires little subsequent activation

In the preparation of saline infusion fluids using charcoal as adsorbent, an opalescent solution is produced on autoclaving under certain conditions This we found to be due to chemical impurities derived from the charcoal The remedy lies either in the use of charcoals prepared by methods (*a*) or (*b*), or in using charcoals prepared by method (c) which has been thoroughly washed to remove all soluble matter It is difficult to determine the method of manufacture of a sample and the BP contains no monograph and standards for activated charcoal, but we found that a suitable charcoal was one which complied with the limit tests and adsorptive-power tests of the United States Pharmacopœia XI, under "Carbo Activatus"

Royal Technical College School of Pharmacy, Glasgow JAMES P TODD, D H

Public Health

Smallpox in Glasgow

As already emphasised in this column a fortnight ago (p 55) the cases fall into two groups (a) those directly associated with the ship which arrived from Bombay on May 29, and (b) those which subsequently made their appearance in the general population Of the cases associated with the ship the first was an electrical engineer, a member of the crew, whose rash appeared on May 23/24 on shipboard and who died on June 2 of confluent smallpox Following a complete medical examination, vaccination or revaccination of all persons on board, the passengers were allowed to proceed to their destinations while the crew remained on shipboard under surveillance some proceeding on temporary leave and others being paid off Subsequently, seven members of the crew, none of whom had been previously vaccinated until May 29, contracted smallpox, all being modified cases with the exception of one who was removed to hospital on June 10 and died on the 15th Two passengers contracted smallpox, the first being a Polish officer who went to a billet near Glasgow, he had been vaccinated in infancy, at 7 and 21 years and again successfully on May 29, his attack being extremely modified The second was a baby who developed smallpox at Swindon, this baby had been vaccinated on May 29 but unsuccessfully One of the medical officers of the Department, who took part in the inspection and vaccination on shipboard, also developed a moderately severe attack He had been vaccinated in infancy and on May 29 unsuccessfully There were thus in all eleven cases connected with the ship, ten being infected from the original case

The second group of cases has occurred in the city population, but in spite of the most rigorous inquiry no connexion has been discovered associating these cases with the ship or with one another The cases which have so far occurred, numbering 25 in all consist of 19 primary and 6 secondary infections The dates of diagnosis and admission to hospital of the first nineteen cases are as follows 26th June 1, 27th June 4, 28th June 3, 29th June 5, 30th June 1, 1st July 2, 2nd July 1, 3rd July 1, 6th July 1 The six secondary cases were admitted to hospital as follows 8th July 1, 9th July 2 10th July 3, two of these cases, however are considered to be doubtful infections Four of the city cases have died in hospital, a woman of 31 a man of 72, a woman of 65 and a woman of 20 who was admitted from a neighbouring town but who received her infection in Glasgow

The original 19 cases occurred at widespread addresses in the East and North of the city but none of them in the dock area The cases themselves have varied between the typical virulent Asiatic type of smallpox and infections so modified as to be difficult to diagnose As each case occurred the immediate contacts were removed to one of the fever hospitals which had been converted into a reception house while vaccination was carried out in the immediate vicinity

Up to June 26 the incidence of smallpox was confined to the crew living on board the vessel When it was found that cases were making their appearance in the city itself, a more serious view was taken of the situation By the morning of Sunday 28th June five patients had been admitted to hospital, one on Friday 26th and four on Saturday 27th On the Sunday during which day three further cases were admitted, it was decided to make arrangements for the general vaccination of the population Arrangements to open twenty-five vaccination centres in schools were made, the staff assembled, the lymph obtained, the forms prepared, the posters and advertisements got ready and the newspapers informed, the centres commencing work on Wednesday morning, July 1

Medical practitioners had already received a letter of June 14 advising them of the occurrence of smallpox among the crew of the ship and requesting them to report any suspicious case in their practices On Sunday, June 28, their cooperation was requested and they were informed of the availability of lymph, the method of vaccination recommended, and the opening of the vaccination centres This was followed on June 30 by a further letter offering a fee of 2*s* 6*d* for each person vaccinated (with the exception of insured persons)

Sir Alexander Macgregor acknowledges his debt to the newspapers for the publicity given to the vaccination scheme On the first day the centres were open nearly 34,000 persons were vaccinated, on the second and third days the number vaccinated on each day was over 55,000 During the first week 282,258 vaccinations were carried out, and up to date (July 16) 375,339 persons have been vaccinated through the centres Returns of persons vaccinated by medical practitioners, at factories, etc, are not yet available but an estimate based on the lymph issued indicates that somewhere about half a million of the population have submitted themselves to vaccination This campaign was thus highly successful One of the results was to give rise to an abundance of vaccinal rashes, some of which were difficult to distinguish from true modified smallpox, and a number of patients were admitted to hospital for observation

It will be observed from this account that the infection in the city began with a group of severe cases, but that subsequent infections have become much less severe and that the more recent admissions to hospital have been known contacts of the original group In these circumstances, the outlook may be regarded as hopeful, although of course there is always the possibility of some unrecognised case continuing to spread the infection, as happened frequently in the 1920 outbreak in the city

Smallpox in Liverpool

A mild discrete case of smallpox was recently reported at Liverpool The patient was a serviceman, returning from Canada after training who reported sick as soon as he joined the ship and was immediately isolated By the time he reached Liverpool he was already convalescent, but he was taken to the isolation hospital until he should have completely recovered All on board the ship were vaccinated and there is no reason to think there will be any secondary cases This case had of course no connexion with the Glasgow outbreak

Infectious Disease in England and Wales

WEEK ENDED JULY 11

Notifications —The following cases of infectious disease were notified during the week smallpox, 0, scarlet fever, 1297, whooping-cough, 1390 diphtheria, 768, paratyphoid, 8, typhoid, 4, measles (excluding rubella), 7361, pneumonia (primary or influenzal) 625; puerperal pyrexia, 182, cerebrospinal fever, 87, poliomyelitis, 5, encephalitis lethargica, 3, dysentery, 155, ophthalmia neonatorum, 106 No case of cholera, plague or typhus fever was notified during the week.

Deaths —In 126 great towns there were no deaths from scarlet fever, 1 (0) from an enteric fever, 4 (1) from measles, 3 (0) from whooping-cough, 13 (1) from diphtheria, 45 (5) from diarrhœa and enteritis under two years, and 9 (2) from influenza The figures in parentheses are those for London itself

Manchester reported the fatal case of enteric fever There were 5 deaths from diarrhœa at Birmingham

The number of stillbirths notified during the week was 215 (corresponding to a rate of 34 per thousand total births), including 19 in London

---

Postgraduate Lectures in Edinburgh —The following Honyman Gillespie lectures will be given at the Royal Infirmary, Edinburgh, on Thursdays at 4.30 P M, during the summer vacation July 30, Dr Andrew Davidson (the contribution of the EMS to medicine and surgery in Scotland), Aug 27, Prof T J Mackie (air-borne infection), Sept 10, Mr T M Millar (perirectal suppuration), Sept 17, Dr Charles Cameron (differential diagnosis of the chronic affections of the lungs), and Sept 24, Mr R L Stirling (sciatica from an orthopædic point of view) The lectures are open to graduates and senior students

Lectures in Ophthalmology at Glasgow — The following lectures will be given in the department of ophthalmology of the University of Glasgow in the autumn Sept 9, Prof W J B Riddell, retinal function, Sept 16, Dr Paul Bacsich, comparative anatomy of the retina, Sept 23, Prof O Loewenstein, PH D, lipoidal changes in the retina, Sept 30, Prof A J Ballantyne, pathology of the retinal veins, and Oct 1 and 2, Mr Eugene Wolff, histology of the retina syphilitic family may alternate syphilitic and healthy children be born? Why may one twin be healthy, the other syphilitic, even in the case of identical twins? Why do the symptoms of the disease vary so much even among the children of the same family? Why do some children respond rapidly to treatment while others need to be treated for three or four years? One explanation may be that some of these cases are not congenital but, as Mr Abraham calls them, "natal" cases. This could only be determined by careful and repeated physical, radiological and serological examinations of the offspring of a syphilitic mother from the time of its birth onwards. These problems, however, would have little more than academic interest if child syphilis—whether congenital or natal—was prevented, *as it can be*, by testing every expectant mother early in her pregnancy and treating those with a positive Wassermann reaction for as long as possible during the pregnancy.

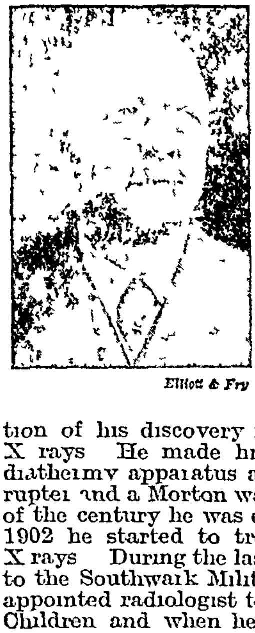
Leatherhead DAVID NABARRO

Obituary

GEORGE BECKETT BATTEN

M D EDIN, F F R, D M R E

Dr G B Batten was the doyen of British radiologists and until shortly before his death on July 9 at the age of 81 was still in practice. He once described himself as a general practitioner interested in radiology and electrotherapy and in many ways he remained a typical family doctor, refusing to reduce the personality of a patient to something to be seen under the X ray.



Elliott & Fry

Batten was born in India, the son of Joseph Hallett Batten, commissioner of Kumoun, and educated at Haileybury College and Edinburgh University, where he qualified in 1881. After holding resident appointments in Scotland he came to Dulwich in 1888 to join John Rand, FRCS, in practice, and when he died he was senior partner of the same firm. Batten had always been interested in electricity. At Haileybury he had made a telephone and within a year of Rontgen's publication of his discovery in 1895 he had begun work with X rays. He made his own coils, high-frequency and diathermy apparatus and also invented a dipping interrupter and a Morton wave apparatus. At the beginning of the century he was experimenting in epilation and in 1902 he started to treat ringworm of the scalp with X rays. During the last war Dr Batten was radiologist to the Southwark Military Hospital and in 1919 he was appointed radiologist to the South Eastern Hospital for Children and when he retired in 1939 he continued to carry on there with civil defence work. His own craft readily recognised his worth and in 1918 as president of the Rontgen Society he described his electrical memories and anticipations. Later he became a foundation fellow of the Faculty of Radiologists.

George Batten was a big man with a large heart and a strong voice. He talked a lot but always had something to say. In his youth he was a great athlete. An enthusiastic swimmer, he played rugby for Haileybury, Edinburgh University and Devonshire. He was an expert on the old penny-farthing and later on a more modern machine won championships in the West of England and in Scotland. He reported his medical reactions to the subject in an article on cycling and perineal pressure to our columns in 1882. As he grew older football and cycling gave way to golf and motoring but he continued to take a versatile and stimulating part in the life of Dulwich. He married Helen Grace Cornish of Penzance in 1888 and he leaves her with a son and a daughter, Dr Grace Batten, DMRE.

JOSEPH BOLIVAR DE LEE

M D, F A C S

Prof J B De Lee, emeritus among American obstetricians, who died at his home in Chicago on April 2, was known for nearly forty years to many of his English colleagues through his wise and lively editorship of the Year Book of Obstetrics. His life was spent in the practice and teaching of his specialty and much of his private fortune was given to the hospitals with which he was associated. The Chicago Lying-in Hospital will be his real memorial and it is fitting that since 1938 its main building has borne his name.

Underwood & Underwood

Joseph De Lee was born at Cold Springs, NY, in 1869, and received his early education at the College of the City of New York. He graduated from the Northwestern University, then known as the Chicago College of Medicine, in 1891, and after two years spent in the medical schools of Paris, Berlin and Vienna he began work in 1894 at a small maternity centre in the middle of the slums of Chicago. He was at once given a teaching appointment in the obstetrical department of his old college and in 1896 accepted the chair. De Lee early recognised the need for maternity beds; in 1895 he undertook the organisation and building of a lying-in dispensary, in 1899 the hospital for maternity care was founded, and in 1917 the first Chicago Lying-in Hospital was opened. In 1931, when this hospital was affiliated with the University of Chicago and a new institution built on the campus, Dr De Lee had already been appointed to the chair of obstetrics and gynæcology of the university in 1929. In 1932 he inaugurated the Chicago Maternity Center and here until his death he served as consulting obstetrician.

Many advances in obstetric practice are due to De Lee's influence. His stout advocacy of local anæsthesia, particularly in lower-segment cæsarean section, or laparotrachelotomy as he termed it, gained many adherents. He first described the use of prophylactic episiotomy in 1920 and he remained convinced of its value in expert hands. The welfare of the infant concerned him only less than the welfare of the mother, and he always wore a head stethoscope for he considered frequent investigations of the fœtal heart sounds were an important guide to the management of labour. But he held with regret that the time had not yet come to discard craniotomy on the living child in severely infected patients. De Lee used the lithotomy position in manipulative deliveries and strongly urged manual as opposed to fixed support of the legs. In a characteristically pungent editorial a few years ago he wrote "I can think of no better education in obstetrics than would come from holding parturients' legs during operations in all the prominent obstetric clinics of the world. If I were younger I'd like to do this. I would be able to write much better editorials."

His friends regretted that one who had done so much for women and children himself remained a bachelor, but outside his work De Lee had only two hobbies—his farm and photography—and even this last was turned to the service of his specialty. He was responsible for many of the films now used in American hospitals and schools, and the new lying-in hospital was equipped for the making of motion pictures. A friend recalls finding him only eighteen days after a gall-bladder operation, wearing his inevitable white tie, engrossed in preparing the setting for one of his pictures. In 1938 he made a pilgrimage to Lanark to visit William Smellie's library, and as an honorary fellow of the Edinburgh Obstetrical Society it was fitting that he should realise his other ambition—to see a Scotsman born in Scotland—at the Simpson Maternity Hospital.

MEDICAL REGISTER.—The names of the following medical practitioners have been restored to the register after removal for omission to communicate an address: Cristina Austin, Peter Carr, Mary J Dodds and Theodotus J Sumner.

THE ONSET OF RESPIRATION AT BIRTH*

SIR JOSEPH BARCROFT, M A CAMB, F R S

THE inspiratory effort is an event so dramatic as to ave stamped itself on the imagination of the idealist s the earnest of a new vital principle, to the realist he first breath is the necessary initiation of life in a new environment To quote the words of Dr. D H Barron: "When an animal is born and begins its truggle towards an independent existence, its first fforts are those of breathing Breathing is living; he onset of respiration is the beginning of life" If I may figure the first breath as a chord struck on an nstrument I may divide a consideration of the subject nto some description of the instrument itself, and some nvestigation of the impact upon it

In the human species a complete series of observations on the development of respiratory movement during the course of gestation would obviously be very difficult—nay, wellnigh impossible Stray observations at present can only be made at cæsarean sections, and then often when the patient (and fœtus) are subject to a degree of anæsthesia which is prejudicial to the more delicate movements The best course open to us is to make serial observations on other mammals to judge what is so fundamental as to constitute a basis of development common to the higher mammals, to separate this from the differences in detail which may be seen from form to form, and to check up the result, so far as man is concerned, by comparison with such human observations as seem from the experimental point of view most unexceptionable.

As a base line no more appropriate animal is available than the sheep Its gestation period, 5 months, though not so long as that of man, is long as compared with those of the smaller animals Unlike the rat, the sheep does not run through the gamut of its intra-uterine development in 21 days, and as the phases of development do not crowd upon one another they are more easily discerned. Moreover, the sheep's fœtus is as large as the human one, and the sheep stands operation extremely well

Can we, from a study of embryonic life, give even a halting sketch of the way in which the instrument of respiration has been elaborated? Mere inspection of embryonic movement at successive stages in the life of the mammalian fœtus tells us much—a body of information substantial enough to stand analysis Movements of the respiratory type during fœtal life have been described by a number of observers, and in several forms of life These observations have done less than they should to fire the imagination of workers, perhaps because they were not connected with any coherent idea of the general motility in the organism Indeed it would scarcely be possible for them to be so connected without a systematic study of the whole relationship of respiratory movements to general motility, a study involving the observation of the fœtus at stated and suitable intervals during its growth

With a sheep under spinal anæsthesia and immersed in a saline bath at body temperature the amniotic sac can be laid bare and the fœtus—at say 30 days—may be seen through the transparent walls At that age the embryo is about the size of the thumb nail, and floats quite freely in the amniotic fluid, attached to the wall by the umbilical cord Evidence of the heart beat may be seen in the cord, but apart from that no intrinsic movement of the embryo is to be discovered.

DEVELOPMENT OF MOVEMENT IN THE FŒTUS

The development of movement generally and respiratory movement in particular may be divided arbitrarily into four stages, the factors which dominate the successive stages, however, do not arise abruptly—the reverse is the case Each stage as it develops imposes itself upon, rather than replaces its predecessors (fig 1)

Stage 1 *Spasm* —The first neuromuscular movement of which the sheep's fœtus is capable takes place about the 34th or 35th day. If the face of the embryo be tapped sharply between the eye and the mouth the head gives a twitch, it is thrown back a little, and at the same time rotated, the nose being turned towards the side which was struck There is only one point the striking of which evokes the movement; and only one movement evoked Removal of the skin shows that the point struck is just over that to which the maxillary branch of the fifth cranial nerve has grown The functionally effective central nervous system at that time thus consists in something very restricted—an afferent path (the maxillary branch of the fifth nerve), an efferent path, which includes the spinal accessory and upper cervical ventral nerve roots and a central connexion between the two (involving cells, presumably those in the recticulospinal tract, connected with the maxillary branch of the fifth)

As each day passes from the 35th onwards this reflex spasm expands in various ways (*a*) The movement can be evoked from the stimulation of other points. For instance, as the maxillary branch of the fifth nerve extends peripherally, the area stimulation of which evokes movement increases, and shortly involves the nose The ophthalmic branch evokes a response and so on (*b*) The muscles used in the spasm increase in number, and by the 38th day the diaphragm has become involved, but only as an item in a generalised movement; nevertheless it is the first movement of a respiratory muscle Of two fœtuses observed on the 38th day, the diaphragm of one gave a single twitch on stimulation of the face, that of the other gave two successive twitches This brings us to the second stage

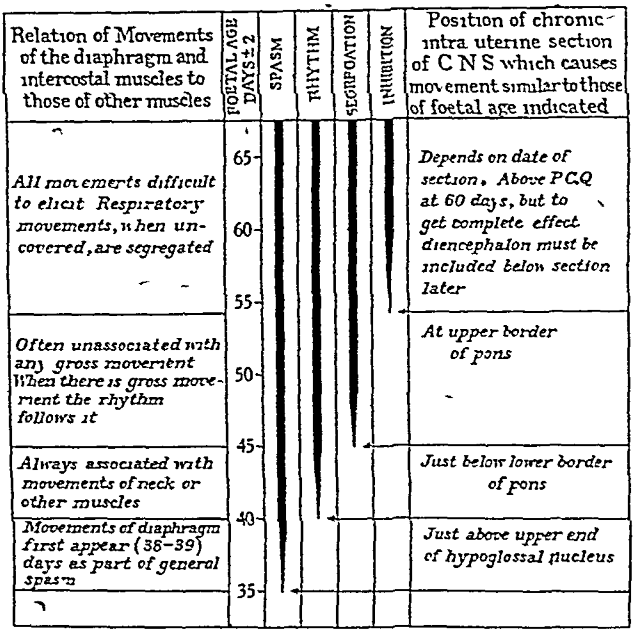


Fig 1

The four stages of development of respiratory and general movement in the fœtus of the sheep

Stage 2. *Rhythm* —By about the 40th day the typical response of the fœtus to a stimulus such as tapping the nose is not merely a spasm but a rhythm of successive spasms As day follows day, the number of spasms which constitute a single rhythmic discharge increases, and the rate also becomes quicker, starting at about 40 to the minute, it rises to over 60 It is in these days that the intercostal muscles are first seen to contract Presumably they do not come into the picture as early as the diaphragm because the spinal centres for the intercostal nerves are lower down the cord than those of the phrenic nerves

Stage 3 *Segregation* —Even as early as the 38th day it was observed that the diaphragm might give two movements when the rest of the body only gave one By the 42nd day careful observation shows that the first one or two spasms in a rhythmic response from the stimulation of the fifth nerve may invoke more muscles than do the subsequent spasms, the respiratory

Notes and News

CONGENITAL BRONCHOCOLIC CANAL

J M Urrutia has come across a case of a congenital deformity which appears to be unique, and from the embryological standpoint inexplicable, in that there was a direct communication between the lower ileum, the splenic flexure of the colon and a branch of the left bronchus (*Rev Sanid milit B Aires* 1942, 41, 83) A seaman of 22 was operated on for acute appendicitis Six days after the operation an abscess in the right iliac fossa was drained This was followed 2 days later by the formation of a *fæcal fistula*, which healed spontaneously after 3 months He continued to complain of dyspepsia and foul-smelling eructations, and shortly afterwards developed left-sided basal pleuropneumonia During this phase, while he was being given a soap enema he complained that he could taste soap in his mouth He was admitted to a sanatorium for further investigation because the lung did not clear up , thence he was sent to the military hospital at Cordoba where he came under Urrutia's care He had a supernumerary nipple on the left side, otherwise there were no obvious clinical abnormalities X-ray examination of the thorax showed slightly reduced translucency at the left base A barium meal showed no abnormality A barium enema was to be given, but the preliminary simple enema was followed by a rigor, temperature of 102° F and " congestion " at the left base Two days later the patient passed a large quantity of blood by the rectum, and had to be given three blood-transfusions He recovered, and a barium enema was then given without incident It showed a track lying parallel to the ascending colon A laparotomy was performed, and a canal was discovered opening from the ileum, 2 cm above its termination, and running upwards along the right side of the descending colon to the splenic flexure, where it appeared to terminate in the bowel It was dissected away Just over a month later the patient had another severe attack of rectal bleeding After he had recovered from this another barium enema was to be given, but again the preliminary enema, which the patient said he could taste in his mouth, was followed by a temperature of 102° F and congestion of the left base Bronchography a few days later showed a canal running downwards from one of the left lower bronchi towards the diaphragm A second laparotomy and further search revealed a canal passing from the neighbourhood of the splenic flexure up towards the diaphragm, about the diameter of a little finger It was isolated and injected with 'Lipiodol,' and a subsequent X ray showed the fluid in both the transverse colon and left bronchial tree The canal was dissected away from the colon and followed as far as the diaphragm, where adhesions rendered further dissection so difficult that the operation was terminated, the track being ligatured and divided and the upper end covered with peritoneum Recovery was uneventful Histological examination showed that the wall of both parts of the canal consisted of three layers, serous, muscular and epithelial, with much inflammatory infiltration

Prof J W H Eyre, emeritus professor of bacteriology in the University of London, has been elected president of the Royal Institute of Public Health and Hygiene in succession to the late Sir Thomas Oliver

University of Edinburgh

On July 15 the following degrees and diplomas were conferred —

Medical Casualties

The following casualties have been announced

Missing presumed killed —T/Surgeon Lieutenant Cameron Fraser, LRCPE, RNVR , A/Surgeon Commander Thomas Clover Larkworthy, MB CAMB, RNVR , and T/Surgeon Lieutenant Eric Beresford Riding, MB LPOOL, RNVR

Missing in Malaya Capt John Anderson Falk, MB CAMB, RAMC

Wounded —W S/Capt John McDonald Dougan, MB DUBL, RAMC

Previously reported POW, now reported wounded and POW —WS/Captain Aidan Robertson Duff, MB EDIN, RAMC

British Dental Association —Mr C Bowdler Henry will deliver a lecture to the association at 13, Hill Street, London, W 1, on July 28, at 3 P M He will speak on the complications and treatment of impacted wisdom teeth

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

Appointments

Wilson, Henry MD CAMB, MRCP, psychiatrist to the London Hospital and to the department of neurology and psychiatry

Colonial Medical Service —The following appointments are announced —

Crabb John, MRCS DTM & H MO, Nigeria
Ground, K E A U , MRCS, DTM & H MO, Nigeria,
Sparrow, C H B , MB SHEFF MO, British Honduras

Births, Marriages and Deaths

BIRTHS

Cardew —On July 12, at Carlisle, the wife of Dr Peter Cardew—a daughter

Gregor —On July 12, at Swanage, the wife of Lieutenant W Gregor, RAMC—a daughter

Latham —On July 13, in London, the wife of Surgeon Lieutenant W J Latham, RN—a daughter

Leigh —On July 10, at Sevenoaks, the wife of Captain A D Leigh, RAMC—a son

Parkinson —On July 11, at Hassocks, Sussex, to Dr Marian Parkinson, wife of Major J P Parkinson, RAMC—a daughter

Stern —On July 13, at Leamington Spa, the wife of Dr E S Stern—a daughter

MARRIAGES

Barker—Muir —On July 16, at Edinburgh, Peter H Lawton Barker, to Alexandrina Kirkhope Muir, MB

Cama—Huntly —On July 16, at Auckland, Leonard Cama, MB, surgeon lieutenant, RNVR, to Joyce Huntly

Kellock—Pollard-Lowsley —On July 7, in London, Thomas Donald Kellock, MB, to Anne Pamela Pollard Lowsley

Neligan—Bell —On July 18 at Oxford, Gerald Anthony Neligan, MB to Marley Constance Bell

DEATHS

Cross —On July 17, at Scarborough, Thomas Brown Cross, MA CAMB, MRCS aged 88

Dalton —On July 13 James Henry Chesshyre Dalton, MBE, MD CAMB, DPH, aged 81

Skey —On July 13, Arthur Richard Harrie Skey MB LOND, surgeon rear admiral RN, of Catisfield, Fareham Hants

TERMINAL ILEOSTOMY IN ULCERATIVE COLITIS

RODNEY MAINGOT, F.R C S
SENIOR SURGEON TO THE SOUTHEND GENERAL HOSPITAL AND TO THE ROYAL WATERLOO HOSPITAL

MANY patients suffering from idiopathic ulcerative colitis respond satisfactorily to a well-planned and prolonged course of medical treatment No specific therapy has yet been devised, and the success of any particular remedy, such as sulphapyridine, sulphaguanidine (Stickney et al 1942), Bargen's serum (Bargen 1936) or antidysenteric serum (Bargen et al 1930), is no proof of its specificity The indications for operation are difficult to define, because the disease is so protean in its manifestations and in the way it responds to orthodox and other types of treatment Nevertheless, it would be accepted by most that surgery is called for where efficient medical treatment has failed to bring about a cure or to produce relief of symptoms, also where certain complications have occurred, such as subacute perforation or abscess, fistula, sinuses, obstruction, massive hæmorrhage or polyposis, or the possibility of malignancy cannot be excluded In the first group are included all those cases which prove intractable to continuous medical treatment conducted under the best conditions in hospital or nursing institution for a period of about six months, and those chronic ambulatory cases which are totally incapacitated for as long as three months or more in each year

OPERATIVE METHODS

Surgical treatment may conveniently be divided into the following

Methods employed for the purpose of irrigating the large bowel—(*a*) appendicostomy, (*b*) valvular cæcostomy

Methods directed to exclusion of the colon from the passage of fæces by means of ileostomy (*a*) simple loop ileostomy, (*b*) terminal (transverse) ileostomy, either end or single-barrelled ileostomy (Rankin 1935) or implantation of the proximal and distal limbs of the divided ileum into separate incisions in the abdominal wall (Cattell 1939)

Ileostomy followed by colectomy with anastomosis of the ileum into the lowest portion of the pelvic colon or into the remaining rectal pouch

Ileostomy followed by total excision of the colon, rectum and anus

Ileostomy followed by restoration of the intestinal continuity—i e, by end to end or side to side ileo ileostomy or ileo cæcostomy

Until recent years appendicostomy has had numerous supporters and there are reports of many cases treated by this method which have apparently responded satisfactorily But in my opinion—and I was at one time an ardent supporter of this operation—there is no convincing evidence that cases thus treated fare better than with efficient medical treatment alone Valvular cæcostomy possesses no distinct advantage over appendicostomy except perhaps that it is easier to perform Neither of these operations places the large bowel at rest, nor does either of them allow the colon to be irrigated in a manner that is unquestionably better than by washing out from below Hurst (1940) and others have shown by simple radiological experiments that the cæcum can always be reached by introducing a pint and a half of opaque medium per anum and that the colon, especially when it is abnormally irritated, as it is in ulcerative colitis, can be completely evacuated by this means There is consequently no advantage in injecting fluid from above Many authorities have in addition questioned the value of colonic irrigations and instillations in the management of this disease They have brought forward evidence to show that washing out the large bowel with weak astringent lotions, tap water, salt solution, 0 8% sulphanilamide in physiological saline, &c has yielded just as disappointing results as instillations of warm olive oil or crude cod-liver oil with its rich vitamin-A content whether these were injected through an appendicostomy opening or per rectum In the majority of cases these injections or instillations instead of alleviating symptoms or hastening the reparative processes in the gut wall seem to aggravate the condition, to induce colicky pains, to cause unnecessary suffering and to increase the number of daily bowel evacuations Cave and Nickel (1940) drawing from their wide experience, state that "Appendicostomy, cæcostomy and, except for certain cases, colostomy have been discarded as ineffectual surgical measures, and have in the past and do at present complicate further surgery when undertaken "

Ileostomy is the operation of choice There are many types of ileostomy, but in a general way it may be stated that loop ileostomy is chosen when the patient has been exsanguinated by repeated severe hæmorrhages or when in the rare fulminating case toxæmia is pronounced Loop ileostomy is a simple emergency measure which is associated with a high mortality, for it is indicated as a last resort in patients who are desperately ill and in whom medical treatment after a reasonable trial has led to no improvement It needs courage to operate on such cases which are extremely exsanguinated or toxæmic, but I have on occasion seen amazing improvement follow within a few days, and eventually complete recovery The operation is performed through a small right gridiron incision under local anæsthesia (Maingot 1940) The lowest loop of ileum is picked up, drawn through the wound, anchored in position, and then decompressed with a rubber catheter It takes but a few minutes to perform, but in a large percentage of cases the patient dies from toxic absorption

The single-loop method of Rankin, which is the simplest of the elective ileostomies, is nowadays rarely undertaken By this plan the terminal ileum is withdrawn through a McBurney or low transrectal incision, the intestine is crushed with enterotomes, divided with a cautery, and after the distal end has been oversewn and inverted with purse-string sutures of silk it is dropped back into the peritoneal cavity and the operation is completed by closing the wound around the protruding limb of intestine, into which a rubber tube is passed and secured to permit of immediate drainage of the bowel The main objections to this procedure are that the distal stump of ileum may blow out, leak or perforate and thus give rise to a virulent spreading peritonitis if for one reason or another the intracolonic pressure remains unduly raised in the immediate postoperative period, as may, for instance, obtain in the case of a stricture of the large bowel, and if at some future date the operation of restitutio ad integrum is contemplated it is more difficult to apply the criteria of cure than if both ends of the divided ileum were on the surface of the abdomen When therefore an elective ileostomy is called for it is better to divide the ileum about 6–8 inches from the ileocæcal junction and to implant the proximal and distal limbs of the intestine into separate incisions in the abdominal wall after the technique advocated and so successfully practised by Cattell A detailed account of this operation is presented in the case-report which follows

In most instances the ileostomy will be permanent It will, of course, be permanent after total colectomy which is performed in two or three stages, where the patient refuses any further operative interference, or where partial or total colectomy or restoration of intestinal continuity is for one reason or another deemed inadvisable or too hazardous

If the disease appears to be strictly limited to the distal half of the colon and proves recalcitrant to medical therapy, colostomy of the end type (Devine 1935) with interruption of the continuity of the bowel can be carried out in the transverse colon, and the distal half of the bowel be resected after it has been defunctioned for several weeks The colostomy is well tolerated and easy to manage, easier in fact than ileostomy, and the late results in these localised cases of the left colon are on the whole satisfactory In about 80% the disease starts in the rectum or pelvic colon and progresses in

---

SIR JOSEPH BARCROFT REFERENCES

Barcroft J (1938) The Brain and its Environment, New Haven, p 44
Eastman N J Gelling E M K and DeLawder A M (1933) *Bull Johns Hopk Hosp* 53, 246
Snyder, F F and Rosenfeld M (1937) *Amer J Physiol* 119, 153
Windle W F (1940) The Physiology of the Fetus, Philadelphia and London, p 85

First, has excessive CO_2 a stimulating effect upon the respiration of the fœtus ? Snyder and Rosenfeld performed a large number of careful experiments chiefly on rabbits They judged of the respiration of the fœtus from the movements which they saw through the uterine wall when the abdomen was open though they checked these up with movements of the abdominal wall in the intact rabbits They state that in 24 experiments embracing 78 fœtuses, excessive CO_2 administered to the mothers produced stimulation of respiratory movements in 8, and had no effect on the other 16 On *the other hand, once the fœtuses were born* CO_2 *exerted* its normal stimulating effect Their conclusion was that "the CO_2 response of the newborn is related to birth rather than to the stage of development" If the CO_2 in the fœtus is reduced, respiratory movements are depressed I take their meaning to be that there is an optimum CO_2 level which is the level normally obtaining in the fœtus

Eastman, Geiling and Lauder (1933) attempted an answer in another way In a number of human deliveries they took samples of the blood from the umbilical cord when the fœtus gave its first breath Applying the carbonic acid content found to the CO_2 dissociation curve of the same blood, they got results so various as to lead them to the conclusion that the onset of respiration was not a simple function of the CO_2 pressure In 1938 I published observations on sheep under urethane in which I could induce no fœtal respiratory movements by the administration of CO_2 to the mother On the other hand, there seems to be no doubt that CO_2 will induce, or at all events accentuate, respiratory movements under suitable circumstances Windle (1940) and his colleagues obtained them in the cat at 44 days Windle's figure shows that a cat fœtus which had been giving respiratory movements off and on at about 2 a minute had them increased up to 33 a minute by administration to the mother of oxygen containing 8% of CO_2 We have observed augmented respiratory movements in sheep where the mother had a spinal anæsthetic and in which the fœtuses therefore had no anæsthetic The following seems to be typical

> "sheep, 83 days' pregnant, was given 10% CO_2 in air, this definitely increased the depth of the respiratory movements which by this time were frequent in any case, owing to exposure Her breathing was much affected The effect of nitrogen alone was much greater, making the fœtus kick about, this it did, even though the mother was not reacting greatly"

This experiment also seems aptly to describe our experiences with regard to oxygen-want The point to emphasise is that respirations of rather a different type are associated with oxygen-want, they are often gasps and generally part of a more extensive muscular movement Moreover, they can be elicited both in fœtuses free from urethane and in those which have had a heavy dose It seems likely therefore that the gasp given by a fœtus in poor condition is liberated by oxygen-want, while in a lively fœtus both oxygen-want and CO_2 excess play a part when the cord is tied Pending more information on this subject, however, it seems desirable to use the word asphyxia to denote that combination of oxygen want and CO_2 excess which is brought about by failure of the placental circulation Certainly the oxygen level in the blood coming from the brain seems pretty accurately to define the limits of asphyxia necessary to invoke respiratory effort This limit varies somewhat with the age of the fœtus but it may be said fairly exactly that if the blood in the sinuses coming away from its brain carries less than a quarter of its possible load of oxygen, a fœtus aged 90–120 days would show respiratory movements, and that this limit gradually sinks to 15% at term

Sensation —A catalogue of the forms of sensation which may conspire to initiate respiration at birth would include reactions to specific sensations as well as a general heightening of the sensibility of the nervous system caused by the establishment of general sensibility on a large scale Moreover, cutting across such a classification would be the division of sensations into extraceptive and proprioceptive

Among specific sensations acting outside the body pain (if such a word can be applied to the experiences of an organism so anoxæmic that it can have no real consciousness) can have a dramatic effect There can be no more specific reaction than that of the gasp in a refractory rabbit's fœtus when the ear is firmly pinched Among specific stimuli from the inside of the body the rise of blood-pressure associated with the cutting off of the placental circulation can possibly be a factor in the initiation of respiration at birth It is not a necessary factor, since examples are on record of animals in which pinching the cord has induced gasping in the absence of hypertension On the other hand in sheep fœtuses in *good condition slowing in the pulse* appears within 5 sec of the rise of pressure caused by the occlusion of the cord, this phenomenon is abolished by section of the vagi and it would seem likely to be a reflex due to stimulation of the aorta or carotid sinus mechanisms or both If so, the possible reactions of these same mechanisms on the respiratory centre cannot be excluded

Among internal sensory impulses those carried by the vagus first occur to the mind, but of course the volley of afferent impulses brought to the brain along the vagus is initiated by the expansion of the chest, and whereas these afferent muscular proprioceptive impulses are all important after the first inspiration, they can scarcely be regarded as a factor in launching the first breath Apart from such specific sensations the general flood of stimuli from the skin and probably from the muscles and the joints are of first importance, for we must remember that at birth not only is the surface of the fœtus exposed to cold and to contact with surrounding objects, but removal of the embryo from its aqueous environments subjects it to the strains put upon it by its own weight No analysis has been made of these varying sensations, but, their accumulated effect is shown by the degree of muscular tone which they invoke A fœtus with its placental circulation intact alternately taken out of and replaced in its bath of saline, exhibits muscular tone to the point of shivering when it is taken out of the bath and relaxation when it is replaced

In the course of a long series of experiments I naturally have been confronted with a number of fœtuses which showed little inclination to breathe even when the cord was ligated In such cases I have found myself implementing the principle set forth above—namely, the initiation of the greatest number of afferent impulses, especially from the sensory endings of the fifth cranial nerve, and then combination with an oxygen supply so copious that when a gasp does take place the blood may acquire as much oxygen as possible, and thus render the brain more receptive to the next sensory volley In practice this amounts to the direction of the stream of oxygen from a cylinder on to the fœtus more especially on to its face, nose, and mouth, once the air passages have been rid of mucus I use the word "stream" not "trickle," because the current of oxygen should stimulate as large a surface as possible, and the atmosphere round the mouth and nose should be rich in that gas The stream of oxygen should, in fact, be as vigorous as is deemed compatible with the welfare of the fœtus always bearing in mind that, unless a fœtus breathes it has no welfare I mention this procedure because I have been occasionally surprised by the dramatic success which has followed it

Remembering that the newborn fœtus has had no respiratory exchange for some time and is therefore overloaded with carbonic acid, I can see little point in adding that gas to the oxygen at this stage, though a certain admixture of nitrogen may be desirable to prevent the lungs collapsing completely should the interval between the gasps be long enough for the complete absorption of the oxygen inhaled At a later stage, when the respiratory rhythm has been established, CO in the oxygen is desirable

Such then is the picture that I draw of the onset of respiration at birth Perhaps it is too much to claim even that it is a picture, rather I regard it as a blocking out of one, for a lifetime might be spent in filling in the details

I wish to thank Mr W S Mansfield and the Cambridge University Farm staff, for providing suitable ewes, and the LCC officials and the staff of the British Postgraduate Medical School who gave me the opportunity to test whether correspondence existed with human cases

References at foot of next page

exploration was conducted nor was the colon palpated to detect the extent of the disease lest infection should be disseminated into the general peritoneal cavity The ileocæcal junction was identified, and as the last few inches of the ileum were involved in the inflammatory process a portion of the intestine about 10 in from the ileocæcal junction was selected for the ileostomy After identifying the lower reaches of the ileocæcal artery, the ileomesentery was cautiously incised vertically on each side so that two or three of the arching blood-vessels could be isolated, tied off in two places and divided, thus allowing a fair degree of mobility when the intestine was transected with an electric cautery Through a small stab wound, which was made at the outer border of the right rectus muscle and was placed slightly above the upper margin of the first incision, a pair of curved artery forceps was passed to clamp the distal ileum Another hæmostat was then applied through the original muscle splitting incision beside it on the proximal ileum, and the bowel was cut through with a cautery, as shown in fig 1 The distal ileal limb was immediately withdrawn through the stab incision and the skin edges were approximated with one or two interrupted sutures of fine silk The bowel was not stitched to the parietal peritoneum as the clamp was left in situ for 5 days, during which time the gut had opportunity to become firmly fixed to the small abdominal incision The proximal or functioning ileal limb was raised and the free edge of the mesentery was sutured to the under aspect of the peritoneum (fig 2) The margins of the peritoneum and rectus muscle were then loosely drawn together around the projecting ileum so that its feeding blood-vessels were not compressed or caught up in any stitch The ileum itself was not sutured to the peritoneum since a fistula is apt to result even when such sutures are introduced cautiously and take up only small bites of the seromuscular coats of the intestine The tension on such anchoring sutures may be very great, with the result that they may cut out or lead to a localised area of gangrene, to subsequent perforation and peritonitis, or to spreading suppuration in the layers of the abdominal wall The wound was closed snugly about the ileum, which was made to protrude about 2 in beyond the sutured incision After removing the clamp on the proximal ileal limb, a rubber tube about the size of one's index finger was introduced into the intestine for 3–4 in and stitched into position with a purse string suture of strong silk The wounds and an area of surrounding abdominal wall were finally protected with wide sheets of flamed 'Elastoplast' (fig 3)

POSTOPERATIVE TREATMENT AND SUBSEQUENT PROGRESS

After four days the discharge from the ileum became too thick to pass readily through the rubber tube, which was led to a bottle underneath the bed, so a small Winsbury-White suprapubic catheter was substituted and drainage was aided by means of continuous suction applied to the distal end of the catheter After the first postoperative week it was found futile to persevere with catheter drainage, and the functioning ileostomy was permitted to discharge freely into voluminous dressings The protective adhesive dressings which were applied directly to the incisions were removed on the 8th day after operation, and after taking out the skin stitches the whole area was thoroughly smeared with ballerina paste (powdered aluminium 1 part by weight, zinc oxide 2 parts by weight, liquid paraffin 2 parts by volume) A special cæcostomy bag made by the Genito-Urinary Manufacturing Co was then fitted on, and as the stump of proximal ileum projected about 1½ in beyond the abdominal wall, most of the corrosive intestinal contents were discharged directly into the rubber bag without much soiling of the skin

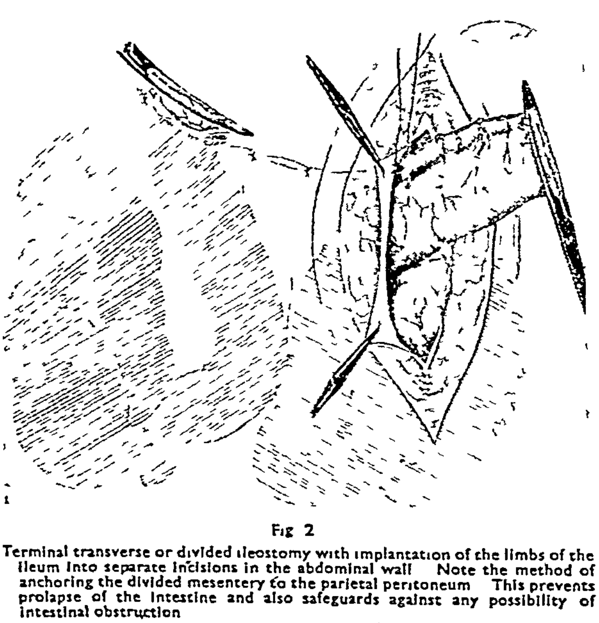

Fig 2

Terminal transverse or divided ileostomy with implantation of the limbs of the ileum into separate incisions in the abdominal wall Note the method of anchoring the divided mesentery to the parietal peritoneum This prevents prolapse of the intestine and also safeguards against any possibility of intestinal obstruction

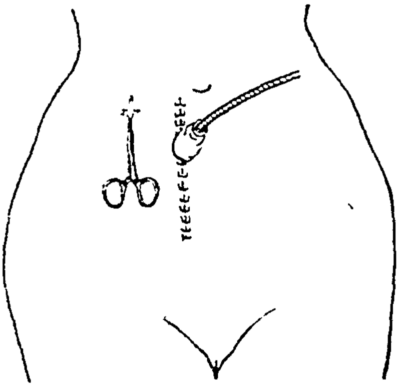

Fig 3

Terminal transverse or divided ileostomy with implantation of the limbs of the ileum into separate incisions in the abdominal wall The operation completed The hæmostat on the distal non-functioning ileal stump remains in situ until it cuts through the bowel wall A rubber tube or catheter has been inserted into the proximal or functioning ileostomy this having been fashioned so as to project some 2 in beyond margin of sutured incision

After this operation the patient made a splendid and uninterrupted recovery, and after instruction on the management of the ileostomy and the ileostomy bag she was discharged on Feb 19, 1940 I do not consider irrigations of the colon of any appreciable benefit in this disease, so we made no use of the distal ileal (mucous) fistula for this purpose

I examined her on several occasions during the next twelve months She was managing the ileostomy bag very well, and on an average there were about 8 ileal motions a day After a while the discharge ceased to be irritating and the skin about the ileostomy stomas was not irritated in any way As she was gaining in weight, as there was no discharge of blood or mucus per anum, and as she was anxious to have the ileostomy closed, she was readmitted for further investigation on Feb 20, 1941, a year after the terminal ileostomy. We now had the difficult task of deciding whether or not the colitis could be regarded as healed, and if so whether it was safe to close the stomas and restore the continuity of the intestinal canal What are the criteria of cure in this treacherous disease ? Well, she had already gained 19 lb in weight, she looked fit and well, she was not anæmic, there was no discharge of blood, mucus or pus per anum, and on sigmoidoscopy the mucous membrane of the rectum and lower sigmoid colon appeared normal and there was no evidence of contraction of the bowel Two litres of normal saline were injected into the colon and retained there for a few minutes After this was expelled and collected, the fluid was centrifuged and the precipitate was examined microscopically for red cells and leucocytes No pus cells or red blood corpuscles were found in the deposit Barium enema X ray examinations of the excluded colon were then carried out, (1) immediately after washing out the large bowel with salt solution, and (2) after a quantity of ileal fæces had been injected through the distal or non-functioning ileostomy The radiograms obtained in the two series were striking In the first series the whole colon looked tubular and contracted—lead-pipe colon—and the usual haustral markings were absent, while in the second series of pictures haustrations were present throughout the large gut which although somewhat spastic and irritable did not appear to possess an unduly narrow lumen in any part of its course It should be remembered that a barium enema X-ray examination of the excluded or defunctioned colon always—or nearly always—shows complete absence of haustral markings, but this would occur if it were entirely healthy, for haustration, as Hurst has pointed out, is the manifestation of the activity of the muscularis mucosæ, the function of which is to mix the colonic contents Thus none occurs in an empty nonfunctioning colon

The final test consisted in introducing certain substances into the colon through a catheter passed into the distal the mucosa and deeper layers of the bowel wall in an anti-clockwise direction until the cæcum or even the last few inches of the ileum are implicated, but in the remainder the ulcerative process is limited to one portion of the bowel or may even have a patchy and bizarre distribution If we exclude the chronic localised cases involving the left half of the colon, for which a defunctioning colostomy followed later by excision of the colon is indicated, then, where radical surgical measures are called for, *subtotal or total colectomy will be the method* of choice as soon as the terminal ileostomy is capable of being satisfactorily managed and the colon is thoroughly rested and rendered as free from infection as is possible

After a subtotal excision of the colon it may be feasible in a favourable case to anastomose the proximal or functioning ileal limb to the stump of the sigmoid colon or even to the rectal cul-de-sac I do not however believe that it is rational to perform an anastomosis between the ileum and sigmoid colon or between the ileum and rectum if there is any disease whatever in the distal segment of intestine If this operation is performed the disease in the rectum or in the remaining segment of large bowel which may be quiescent is apt to be lighted up, to progress apace and eventually to produce a pelvic abscess, abdominal or peritoneal sinuses, or suchlike complications But where there is good evidence that the long-rested and excluded rectal pouch or rectosigmoidal segment is healthy and has remained staunch for at least a year after terminal ileostomy and partial colectomy, implantation of the liberated ileal limb into the small remaining stump of large bowel may be considered, and it is only when it is carried out in such favourable circumstances that the operation has anything to offer

I have previously stated that in most cases the ileostomy is permanent, but " there is one favourable feature in the treatment of these cases if early ileostomy is elected When in the past we have considered ileostomy as a permanent necessity in these cases, in the last five years we have been able to close the ileostomy with restoration of intestinal continuity in four patients in whom ileostomy was done early and satisfactory healing in the colon followed It seems possible that if early ileostomy is done in some of these cases, closure of the ileostomy may be done more frequently " (Cattell 1939) The number of reported cases in which it has proved possible to perform ileo-ileostomy or ileocæcostomy and thus restore continuity of the intestinal stream have been scanty Cave and Nickel (1940) reported 22 cases, Bancroft (1940) 4, and Cattell (1939) 4, while Stone (1940), Strauss (1923), Trout (1936) and others (Maingot 1940, Miller 1940) have recorded similar cases and given an account of their experiences with ileostomy followed by closure

In view of the rarity of the operation of ileo-ileostomy or ileocæcostomy following terminal ileostomy for ulcerative colitis and of the great difficulty experienced in deciding which cases are in fact suitable for this procedure, the following details of a " successful " case are submitted I use the word successful guardedly for it is impossible to say that after any given period of freedom from activity the disease will not recur, so long as the colon remains in situ one cannot regard any case of ulcerative colitis as permanently cured, and in no fewer than 25% of the recorded cases recurrence followed ileostomy with subsequent closure My patient is perhaps fortunate in having survived terminal ileostomy, which is associated with an all-round fatality of about 30%, and also ileostomy with subsequent closure, which has a fatality of about 20%, furthermore, some fourteen months after restoration of the intestinal stream she has gained over 28 lb in weight, her bowels act only once a day and without the aid of aperients, the fæces are well-formed and free from any trace of blood or mucus, her appetite is good, she is doing a full day's work and she looks the picture of health

CASE-REPORT

A married woman, aged 28, was admitted to the Southend General Hospital on Nov 8, 1939, complaining of severe abdominal pain, vomiting, diarrhœa, the passage of blood in her motions and a feeling of exhaustion She enjoyed good health until November, 1935, when she started to get recurrent colicky pains in the abdomen and suffered from tiredness About two years later she passed blood in her motions, had attacks of diarrhœa, and started to lose weight Abdominal cramps often preceded a bowel movement In October, 1939, she was treated for three weeks at a general hospital as a case of acute ulcerative colitis before being referred to me

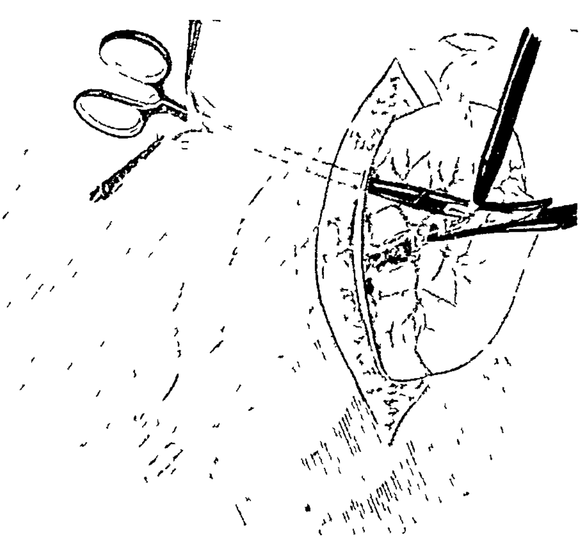

Fig 1

Terminal transverse or divided ileostomy with implantation of the limbs of the ileum into separate incisions in the abdominal wall The mesentery of the ileum has been divided and the intestine is being severed between hæmostats with an electric cautery

She appeared to be gravely ill and exhausted, her mind was confused and she was uncooperative and petulant The temperature was high and remained so for several days, the pulse rate was rapid, the respirations somewhat hurried, the face flushed and the eyes hollow and glistening Signs of dehydration were present, the tongue being dry and brown and covered with dirty fur The abdomen was slightly dome shaped and was tender on palpation Rectal examination, which was painful, was followed by a gush of highly offensive dark red slimy liquid fæces The pelvic organs were normal and the kidneys could not be palpated There was œdema of both lower extremities During the first week after her admission she was passing 10–15 blood stained motions in each 24 hours The urinary output was scanty and the urine contained a trace of albumin and acetone

Bacterial examination of the fæces revealed no specific causative factor, and the patient's serum failed to agglutinate any of the various strains of *Bacillus dysenteriæ* Blood investigation showed a secondary anæmia, and the blood urea was 54 mg per 100 c cm Proctoscopy and sigmoidoscopy followed by barium enema X ray examinations and contrast enemas supported a diagnosis of idiopathic ulcerative colitis There was no evidence of pseudopolypi or strictures of the colon

She was given a brief trial of medical treatment which consisted of repeated small blood transfusions of freshly citrated blood, vitamins A, B, C and K in adequate dosage, a course of sulphapyridine (32 g in 5 days), sedative drugs such as 'Nepenthe,' phenobarbitone, codeine, &c, an easily assimilable diet containing a generous protein content, and daily instillations per anum of 4–5 oz of crude cod liver oil She showed some all round improvement on this regime, but on Nov 23 she relapsed and became gravely ill and toxæmic She was now passing about five stools a day, but the blood loss was not so pronounced

FIRST OPERATION

Terminal ileostomy with implantation of the proximal and distal limbs of the ileum into separate incisions in the abdominal wall was performed under cyclopropane anæsthesia on Nov 25 A vertical incision 3 in long was made over the lower half of the right rectus muscle at the junction of the inner and middle third, starting below and slightly to the right of the umbilicus The muscle was split in line with its fibres, the peritoneum was opened and each margin was picked up with hæmostats and retracted, and the last 2 ft of the ileum was drawn on to the surface of the abdomen No pale but not very ill, the cervical, axillary, inguinal and epitrochlear glands were enlarged, and although there was a slight cough the lungs showed no abnormal physical signs The heart also appeared normal and throat healthy There was some tenderness and rigidity over the gall-bladder, but neither the liver-edge nor the spleen was palpable Urine normal There was no trace of a rash, nor any history of one While at the reception station there had been a rise of temperature to 101° F but the temperature while in hospital remained normal Pulse- and respiration rates were normal throughout X-ray examination of chest showed no enlargement of mediastinal glands His convalescence was uninterrupted, and he was discharged from hospital on Jan. 6, 1942

These two cases present the same clinical features as those reported by Martin In case 1 the jaundice was prominent and was in evidence before the lymphatic glands became enlarged, in case 2 the jaundice was mild and transient and appeared early in the course of an attack of glandular fever The positive direct van den Bergh test in case 1 suggests that the jaundice was of obstructive origin

In order to ascertain if the association of glandular fever with jaundice was being missed or overlooked, I asked medical officers to have blood examinations done and a careful search made for enlarged lymphatic glands in patients with jaundice, but in no instance yet have cases similar to the above been discovered

I should like to thank Major General G A Blake, K H S, deputy director of medical services, Western Command, for permission to publish these notes

SKIN-PIGMENTATION WITH DEMENTIA

ARTHUR HARRIS, M.D MANC, D P M
MEDICAL OFFICER AT ST FRANCIS MENTAL OBSERVATION UNIT, LCC

A MAN of 37 was admitted to the observation ward from an institution to which he had been sent because he was destitute The history given by a former employer was that the patient began to work for him 10 years ago at distributing handbills There was then nothing remarkable about him, his skin was quite white and he did his work well Some years later his employer noticed that the man's skin was getting darker and that he was deteriorating mentally, becoming vague, unable to concentrate and extremely unreliable, often coming back with his handbills undistributed Four years ago because of this he had to discharge him There is then a gap in the patient's history until 3 months before his admission when he took the two rooms from which he was removed to the institution He soon fell out with the landlady because of the filthy state in which he kept them and she was forced to send for the sanitary inspector

From the patient s father it was learnt that he came from an old Yorkshire family on the father s side and that his mother's people were Londoners No admixture of foreign blood was known of, but his father s family tended to be dark skinned and to sunburn easily, although not to a strikingly abnormal extent He had always been obstinate, self-centred, quarrelsome, with an exaggerated idea of his own importance, and very lazy with regard to his work, but exceptionally neat and tidy and careful of his personal appearance He was backward at school and since had never been able to keep a job longer than eight or nine months on account of his personality defects and clumsiness, incompetence and apparent stupidity His mother, for whom he had a strong fixation, died when he was 25 years old, his father remarried a year later and he then became violently antagonistic both to his father and stepmother After constant quarrels he left home at the age of 29 and his family did not hear of him again until notified that he had been removed to hospital

He was elated, on admission, and paraded round the ward in a grandiose, hyperextended attitude, declaring that he was "in the pink, as strong as a lion and a hundred per cent" His movements were unnecessarily violent, erratic and jerky, for example, if asked to lie down he would throw himself back in a manner likely to break the mattress Although he talked incessantly he made the same remarks over and over again, many hundreds of times, varying his phraseology little all the time he was under observation He usually prefaced his remarks by saying that doctors were his friends and went on to ask for his discharge as he was very worried about his flat If one returned to him some ten minutes later he would reproduce the whole speech almost word for word He showed no gross disorientation or amnesia and could answer simple questions fairly accurately. He micturated and defæcated shamelessly in the middle of the ward and showed no appreciation of the quality of this behaviour

There was a generalised brownish yellow pigmentation of the skin, fairly evenly distributed but rather deeper on the face and neck and much deeper on the scrotum and nipples, which were almost black. The buccal mucous membrane showed bluish patches, chiefly on the gums and sides of the tongue There was some dental caries but no pyorrhœa or localised stomatitis Apart from the pigmentation, the skin and mucous membranes appeared quite healthy with no evidence of infestation by parasites, and no scratch marks His hair was thin and the top of his scalp bald The only constant abnormality found in the central nervous system was extensor plantar responses, although at different times a slightly irregular pupil on the left side and absent abdominal responses on the right side were noted There were no abnormalities in the cardiovascular system and the blood-pressure was 120/80 mm Hg on two occasions, after resting in bed for some hours The respiratory system and abdomen were normal There was no evidence of enlargement of liver or spleen His thyroid was not enlarged and there were no signs of hyperthyroidism or other endocrine disturbance. The Wassermann reaction was negative in the blood, and also in the CSF which was otherwise normal, with a negative Lange curve, a protein content of 50 mg per 100 c cm and a cellular content of 3 lymphocytes per c mm The urine contained no albumin, bile or excess urobilin, did not reduce Fehling's or Benedict's solutions and did not darken on standing The blood showed no abnormality, Hb 90%; red cells 4,500,000, colour-index 1, white cells 7800 (neutrophils 65%, lymphocytes 28%, eosinophils 5%, monocytes 2%) The hair was analysed for arsenic but none was found

DISCUSSION

The cutaneous pigmentation resembles accurately that found in Addison's disease and mulattoes, but the former can be excluded by the normal blood-pressure and absence of asthenia and the latter by the history The dementia is remarkable for the early age of onset and the slowness of its progress, these with the neurological signs, suggest a diffuse cortical atrophy Features of any conditions in which pigmentation of the skin is associated with dementia (such as pellagra, neurofibromatosis and metallic poisoning) are absent

Pigmentary abnormalities are not uncommonly associated with neurological disorders, but they are patchy and usually resemble a vitiligo (Ellerman and Schroeder 1933) Cases have been described in which pigmentation of the skin is associated with pigmentation in the brain (Grahl 1906, Maclachlan 1913 Kessler 1937); they are usually regarded as benign nævi but they have all been in children and there is no record of any progressive mental deterioration having occurred The malignant melanoma, which is not so rare, progresses fairly rapidly to a fatal issue (Farnell and Globus 1931)

I wish to thank Miss M G Seward, psychiatric social worker to St Francis Hospital, for investigating the history, and Dr O W Roberts, medical superintendent of the hospital, and Dr Allen Daley for permission to publish this case

DOSAGE OF MEPACRINE —In an annotation last week (p 102) on the successful treatment of giardiasis by mepacrine ('Atebrin' Bayer) the dose of 0 1 g was incorrectly printed 1 gramme The slip is serious since the margin between therapeutic and toxic doses is not very wide and it is the more unfortunate because the maximum dose of mepacrine hydrochloride was incorrectly given in the BP Third Addendum (p 15) Zeus is not often caught napping and the error was picked up in the Fourth Addendum nine months later But it should be reiterated that a whole gramme is an excessive dose ileal stoma to ascertain what the colon could tolerate The following were injected milk, albumin water, oatmeal gruel and then diluted ileal fæces The fæces, which were discharged through the proximal ileostomy, were collected and at first diluted with water, then gradually made stronger until eventually the whole of the ileal discharge was introduced into the colon undiluted The ileal contents were well tolerated in the colon, the bowels were evacuated once or twice a day, the stools being well formed and containing no blood or pus As there were no signs of a flare up of the active process after several days of testing and training the large gut, it was decided to re join the divided ileum

SECOND OPERATION

Closure of the ileostomy stomas followed by side to side ileocæcostomy was performed on Feb 8, 1941, under endotracheal gas oxygen-ether anæsthesia Both ileostomy stumps were dissected from the abdominal wall, invaginated and closed, and as the distal limb of the ileum was atrophied and somewhat sclerosed it was amputated about an inch from the ileocæcal junction, the stump of the ileum being invaginated into the capacious cæcum through the ileocæcal valve, and two purse string sutures of silk were used to close the defect in the cæcal wall The appendix was long and tortuous and contained many fæcaliths It was therefore amputated and its stump invaginated with a purse string suture The ileum which was prepared for anastomosis was then joined to the anterior aspect of the cæcum and an isoperistaltic side to side anastomosis was fashioned in the usual manner with the aid of enterostomy clamps The abdominal incisions were approximated in layers and the wounds sealed off with adhesive plaster impregnated with sulphanilamide

POSTOPERATIVE COURSE

The wounds healed well, the bowels acted without enemata or aperients on the fourth postoperative day, and after that there were one or two daily evacuations while she was in hospital She was discharged on March 28, 1941, and reported every two months afterwards She was examined for the last time in April, 1942, when she was found to be well in every respect

SUMMARY

Surgery is indicated in idiopathic ulcerative colitis where efficient medical treatment has failed to bring about a cure or produce relief of symptoms, and where certain complications have occurred, such as fistula, sinuses, obstruction, subacute perforation or polyposis, or the possibility of malignancy cannot be excluded

The operation of choice is terminal ileostomy, preferably with implantation of the proximal and distal ileal limbs into separate incisions in the abdominal wall Such operations as appendicostomy, cæcostomy, &c, which were employed for the purpose of irrigating the large bowel, have now been more or less abandoned The various operative procedures together with a choice in individual cases are briefly discussed

A case of idiopathic ulcerative colitis which was successfully treated by terminal ileostomy followed a year later by restoration of intestinal continuity is described The difficult problem is to decide whether or not the colitis can be regarded as healed after terminal ileostomy, and if so whether it is safe to close the stomas and restore the continuity of the intestinal canal

GLANDULAR FEVER WITH JAUNDIC

Robert Priest, C B, M D Camb, F R C P
BRIGADIER, CONSULTING PHYSICIAN TO THE WESTERN COMMA

The publication by Martin[1] of two cases of the un
occurrence of glandular fever with jaundice has prom
me to submit an account of two very similar cases

Case 1 —A lieutenant, aged 28, was admitted to a
hospital in France on Feb 29, 1940, complaining of the gr
onset of headache, of feeling feverish, and of shivering
general weakness over the preceding 3 days The head
was mainly behind the eyes, the fauces were injected,
with the exception of some mild bronchitis there were no
abnormal physical signs On March 1 there was a rise in
perature, but nothing was found on examination to acc
for it Urine normal Next day there was some epist
the headache persisted, and he was coughing and bringin
a little numular sputum, a slight icteric tinge in the s
tics was noticed Liver edge palpable below the right c

THE LANCET

LONDON, SATURDAY, AUGUST 1, 1942

THE HOSPITAL'S LIABILITY

IF hospitals are not always pleased with patients, patients are not always pleased with hospitals Litigation against the latter may be expected to increase as the result of the Court of Appeal's recent decision in Gold *v* Essex County Council Ever since 1909, when Lord Justice KENNEDY gave his oft-quoted views in Hillyer *v* St Bartholomew's Hospital, a hospital has enjoyed a certain immunity when sued for damages for the alleged negligence of surgeon, doctor or nurse The maxim *respondeat superior* carries important consequences, but there is no liability unless the relationship of master and servant be present "It is open to argument," said the trial judge in the Hillyer case, "how far the professional staff of one of our English hospitals comes under the title of employees, but it seems obvious that, if the authorities have done their best to secure a competent staff, their liabilities should cease there, as they cannot possibly supervise by personal attendance the work of the physicians and surgeons in the wards" This is the principle which Lord Justice KENNEDY endorsed Now the Hillyer decision is overthrown Leave has been given to take the matter to the House of Lords, but, unless the supreme appellate tribunal reverses the Court of Appeal, the textbooks must be corrected and hospitals must consider how to cover their increased risks of adverse verdicts

Ruth Gold, a five-year-old child, was treated at the council's Oldchurch hospital at Romford for the removal of warts on her face by grenz rays Mr Mead, the radiographer, a full-time salaried employee of the hospital, on one occasion used a screen of lint instead of the usual mask for the face, the result was permanent scarring and disfigurement In the King's Bench Division Mr Justice TUCKER held that Mr Mead had been negligent but that the county council was not liable, the council's sole duty was to provide a competent radiographer, Mr Mead, though negligent in this instance, was indisputably competent The trial judge was bound by the Court of Appeal's view in the Hillyer case The Court of Appeal has now ingeniously cut down the supposed authority of that view Lord GREENE, the Master of the Rolls, analysed the decision of 1909 He found that his predecessor (Sir RICHARD HENN COLLINS) had given no reasoned judgment but had simply concurred with his two colleagues Of these two colleagues Lord Justice FARWELL had decided on narrow grounds in favour of St Bartholomew's Hospital, Lord Justice KENNEDY on unnecessarily wide ones Lord GREENE takes the narrow view as the true *ratio decidendi* Lord Justice FARWELL, he considers, was examining the position of hospital authorities only in relation to what took place in the operating theatre Nothing in the Farwell judgment supported the view that hospital authorities were not liable for the negligent acts of nurses in performing general duties of a purely administrative or domestic nature, such as giving a patient his meals The true ground, said Lord GREENE, on which a hospital escaped liability for the act of a nurse who, whether in the operating theatre or elsewhere, was acting under the instruction of a surgeon or doctor, was not that she ceased for the time being to be a servant of the hospital but that she was not guilty of negligence if she carried out the orders of the surgeon or doctor The reasoning of the Farwell judgment did not cover such a case as Mr Mead's Mr Mead did what he did on his own judgment, he was not under the orders of a medical man except as to the nature of the treatment and the dose Lord Justice KENNEDY's view was that the hospital authority's sole liability was to take care that the patient was treated only by experts of whose competence the hospital had taken pains to assure itself and that the available apparatus was proper This view was that of Lord Justice KENNEDY alone, there was no legal authority for it in England, it went beyond the scope of the Hillyer case and was therefore a mere dictum, the Court of Appeal was free to disregard it and to consider the matter afresh "I cannot see," observed Lord GREENE, "that hospital authorities do not undertake towards a patient the duty of nursing him as distinct from the obligation to provide a skilful nurse" The Romford Hospital assumed the obligation to treat Ruth Gold by the hands of Mr Mead with the apparatus provided The county council's liability was established, the negligence of its servant was clear, the damages were assessed at £300

The Master of the Rolls, it will be seen, does not favour the idea that a hospital undertakes the obligation to perform by its nursing staff only administrative work and not the essential work of nursing This idea he described as unworkable in practice and indeed contrary to common sense Lord GREENE's important opinion seems to deal more fully with a hospital's responsibility for a nurse than with its responsibility for other professional staff Is the surgeon, if he be negligent, equally the servant of the hospital? And is there any distinction between a surgeon who holds an honorary staff appointment and a whole-time salaried officer? Presumably no difference can be discovered between the liability of a voluntary hospital and that of one which is conducted by a local authority under statutory powers and duties, although in practice a plaintiff may be aware that juries (temporarily in abeyance) may be more generous at the expense of the latter Many important cases have lately been luminously reviewed in the House of Lords where Lord SIMON presides It may be hoped that the Essex County Council's appeal will give hospitals the clear lead for which they are waiting

THIRST AT SEA

WHEN the mammals left the sea, the fluid which bathed their cells was presumably isotonic with sea-water, but since then while the sea has got salter our internal environment has not, until now the sea contains some 2 7% of sodium chloride and our blood but 0 9% Neither have we acquired in these æons any mechanism for the selective absorption of water from a hypertonic solution—sea-water in the stomach will abstract fluid from the tissues by osmosis and not vice versa Thirty years ago MORLEY ROBERTS suggested that such a mechanism does exist in the rectum, and he later[1] backed his theory with the tale of Mr Graham, "for whose bona fides many well-

Reviews of Books

Diseases Transmitted from Animals to Man

(2nd ed) THOMAS G HULL, Ph D , director, The Scientific Exhibit, American Medical Association London Bailliere, Tindall and Cox Pp 403 30*s*

COMPARATIVE medicine has made strides in the past decade, the veterinarian, the pathologist and the epidemiologist are realising the interrelationships of their various problems, and with increasing research in veterinary diseases the liaison between "animal" and "human" pathologists has become much closer A book on diseases of animals transmissible to man, therefore, comes at an opportune time, and will appeal to field as well as laboratory worker because it discusses the spread and control of such infections In this second edition (published 11 years after the first) Hull has enlisted the help of expert collaborators to revise some sections and to write others afresh The result has been to accumulate much interesting and exact information, not otherwise readily available The book deals with diseases of domestic animals and birds, rodent infections, human diseases spread by animals (sore-throat, scarlet fever and diphtheria), animals as passive carriers of disease organisms (the pathogenic sporing anaerobes), and the rôle of the common animals in the spread of disease There is little to criticise and much to commend For example, the virtual eradication of bovine tuberculosis in the United States is an achievement which has had too little publicity in this country where the obstacles are too easily regarded as insuperable The risk of spread of avian tuberculosis to pigs—the pigeon seems to be a common culprit—must not be forgotten Data are presented on anthrax as an industrial hazard, 36 pages are devoted to rabies, and the animal-man relationships in plague, tularæmia, leptospirosis, and the rickettsias are well described although more space might have been given to the rôle of animals and birds as reservoirs of the salmonella food-poisoning bacteria Psittacosis is quoted as a rare example of an animal disease which may be transmitted from man to man In the last chapter the results to man of his domestication of animals and birds are epitomised The book is beautifully produced and liberally sprinkled with maps and photographs

Treatment of Shock

R W RAVEN, F R C S , major R A M C , assistant surgeon, Royal Cancer Hospital (Free), London London Humphrey Milford, Oxford University Press Pp 96 5*s*

Major Raven has attempted to combine in small compass a critical monograph and a didactic textbook In a large measure he has succeeded in giving a clear and well-balanced account of our present knowledge of shock and its pathology Though he considers that the customary classification of shock into primary and secondary is not entirely satisfactory, he has—perhaps unwisely—used the old nomenclature, here was an opportunity for originality His descriptions are brief and to the point—though the illustration of the crush syndrome in the frontispiece suggests a simpler interpretation He holds three measures to be of paramount importance in the treatment of secondary shock elimination of noxious stimuli by preventing unnecessary movement, pain and loss of heat, restoration of fluid volume by transfusions of whole blood or plasma, and oxygen for prevention and treatment of anoxia About half the book is devoted to the treatment of oligæmia and anoxia and he emphasises that mobile transfusion units are needed as close to the fighting as possible The expert may quibble at some minor statements, but taken as a whole this little book fills a gap in the field of war medicine, and it is just the right size to be carried in the pocket

Child Welfare and School Medical Work

A Handbook for Assistant Medical Officers of Health
F J G LISHMAN, M D Lond , D P H , deputy MO for Devon London H K Lewis Pp 70 6*s*

THIS little book is made up of a series of leaflets originally issued by Dr. Lishman for the guidance of assistant county medical officers of Devon, many of whom were new to the work required of them He has wisely published them in book form for general use since owing to the war many assistant medical officers have to be appointed without previous experience of public health work and there is neither the time nor the opportunity to give them the usual introduction to their duties The book has another value in fixing what is the scope and limit of the public health officer's share in the province of personal medicine, those who read it without bias should be convinced that the individual public health services are ancillary and not in opposition to the work of family physicians

Year Book of Dermatology and Syphilology, 1941

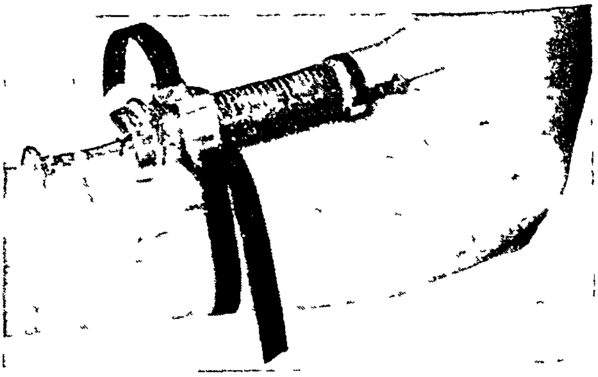
Editors FRED WISE, M D , MARION B SULZBERGER, M D Chicago Year Book Publishers, London H K Lewis. Pp 692 16*s* 6*d*

THIS handbook with its concise abstracts of the best articles on dermatological subjects published during the past year has as usual achieved a high level About a fifth of it deals with syphilis The introductory article by the editors is on seborrhœic dermatitis, and an attempt has been made to clarify the subject They give the lie to some old conceptions and unfounded statements that have been handed down from textbook to textbook thus they state that the *Pityrosporum ovale* is a saprophyte living on a seborrhœic skin, a soil which favours its propagation, and they consider that its rôle as a primary causal factor has not been established Similarly they maintain that there is no real evidence that seborrhœic dermatitis is contagious either by brush, comb or anything else This is almost certainly true The article finishes with a section on treatment containing many serviceable prescriptions

New Inventions

A "THIRD HAND" FOR INTRAVENOUS ANÆSTHESIA

IN keeping with the growing popularity of intravenous anæsthesia, particularly with 'Pentothal Sodium' (Abbott), various more or less elaborate methods have been described for continuous administration Many anæsthetists however prefer the simplicity of a 10 or 20 c cm syringe with the needle directly affixed, and for short operations this is satisfactory Not infrequently the anæsthetist's attention is diverted to support the jaw or to assist in moving the patient during administration In such circumstances the simple device illustrated has proved its usefulness



It consists of a strip of brass ½ in wide bent at a right angle and perforated at each end by a rectangular hole Each limb of the metal strip is covered by a small section of rubber tubing, the barrel of the syringe being held in the angle between them A piece of rubber from an old inner tube passes round the patient's arm and through the holes in the metal The rubber fits the holes tightly but when traction is applied to the ends it can be drawn through and released when the desired degree of pressure has been exerted

The manufacturers are Medical & Industrial Equipment Ltd , of New Cavendish Street, W 1, and Messrs. A C King Ltd , of Devonshire Street, W 1

I. W MAGILL, M B , D A

logy and psychiatry offers no such easy arrangement In present-day controversy some neurologists deny the validity of psychological conceptions, and psychiatrists counter by denying the right of neurologists to concern themselves with the subject, ascribing their association with it to the joint influence of tradition and a misleading nomenclature This difference appears to rest upon unrecognised, and therefore unexplored, metaphysical assumptions about body and mind, and offers little prospect of solution by any process of digestive assimilation It should not, however, hinder the cooperation of tolerant exponents of each specialty, for which the new department at the London offers an opportunity Psychiatry will be able to show its value in the daily work of the hospital, and here its scope is wide the psychoses can be demonstrated in those early stages that so often puzzle the practitioner, the recognition of a psychoneurosis will no longer mark the end of clinical interest in a case even if treatment offers practical difficulties, and, perhaps most important of all, the psychosomatic disorders we are now coming to recognise will present new opportunities for the advancement of clinical medicine

TREATMENT OF ULCERATIVE COLITIS

THE management of ulcerative colitis resolves itself in the acute or fulminating case into keeping the patient alive and in the more chronic progressive case into keeping him reasonably fit None of the specific forms of treatment tried out has proved universally effective, but certain general principles have been established STREICHER,[1] from experience with 912 cases, summarises the management of the acute cases as being mainly supportive, with rest in bed, small repeated blood-transfusions, a diet with plenty of protein and vitamins, including vitamin K, opium and hydrochloric acid by mouth, and parenteral injections of liver extract In chronic ambulatory cases a diet rich in protein and vitamins is again needed, with opium to control the frequency of motions, phenobarbitone to allay restlessness, iron, dilute hydrochloric acid and liver extracts for anæmia, and removal of any foci of infection It is sometimes advisable to begin treatment with a course of emetine, gr ½ hypodermically twice a day for four or five days, and of carbarsone in 4-grain capsules by mouth twice a day for ten days, even in the absence of dysentery bacilli or amœbæ, for occasional cases respond, as a few others do to vaccine therapy

As with all chronic diseases which tend to progress or relapse without apparent reason there are waves of fashion for certain remedies, and in the past few years trial has of course been made of the sulphonamide drugs On the whole the results with sulphanilamide so far published are disappointing, acutely ill patients may be considerably upset with vomiting, increased diarrhœa and abdominal cramps Benefit has been reported from sulphathiazole given in gr 15 doses every four to six hours for five to seven days Sulphaguanidine, being less readily absorbed from the intestine, produces a higher concentration in the gut without toxic effects, and in a few cases has been strikingly successful The new drug sulphasuxidine, which is even less readily absorbed, may prove more successful still Local irrigation of the colon with silver nitrate and antiseptics has been largely superseded by using colonic douches of normal saline or rectal injections of vitamin A such as is contained in 4–6 oz of cod-liver oil In such a chronic disease, liable to relapse, it is difficult to follow up cases to obtain an estimate of prognosis, of cases traced over years, about a fifth may be regarded as cured and another three-fifths show considerable improvement

It is in patients who become progressively worse in spite of careful conservative treatment that surgical measures should be considered The most accepted opinion is that if some drainage operation is undertaken an ileostomy is the one of choice On another page MAINGOT reviews the indications for surgery and discusses the various operations Local rectal states, fissure or abscess, and abdominal emergencies—perforation and obstruction—clearly need surgical intervention Acutely ill patients, whether primarily or in relapse, stand operation badly The mortality in these cases is prohibitively high, in cases where ileostomy is done after careful consideration a fatality of 20% is usual[2] MAINGOT's case, with most careful handling, responded to a terminal ileostomy by complete recovery of colonic tone and function so that bowel continuity could be successfully restored by anastomosis of the proximal end of the ileum into the cæcum This procedure, which cannot often be carried through, must leave the patient much nearer normality than does ileostomy with subsequent colectomy Yet KAHN and BAY[3] advocate total colectomy, done in three stages, because it completely disposes of the diseased bowel, results, they say, in no permanent damage to the patient and has a reasonable mortality (5 deaths in 51 published cases) In all chronic cases careful observations of the rectosigmoid by direct vision and of the motions must have demonstrated the absence of any active lesion of the colon before any relaxation of careful medical treatment or restoration of bowel continuity after ileostomy is allowed MAINGOT's final test of healing was to inject milk, albumin water, oatmeal gruel and finally decreasing dilutions of ileal fæces into the distal ileal stoma and to watch for signs of intolerance or a flare up—an obviously sound method

WHIPWORM AS A CAUSE OF SYMPTOMS

INFESTATION with *Trichuris trichiura* is almost universal in the tropics and is quite common in English country districts No systematic search for it is under taken because it is generally regarded as non-pathogenic In Ross's patient, described in our columns last week (p 97), the symptoms were chronic diarrhœa for five years, some abdominal pain, breathlessness and fatigue, the case was remarkable for the heaviness of the infestation, of which the numbers of dead worms—1000 or more—excreted after treatment were a measure The parasite is described as being resistant to most anthelminthics, Faust does not in his monograph[4] record treatment of whipworm infections with hexylresorcinol, and its successful use by Ross is thus an advance Diagnosis by means of the sigmoidoscope is also new, no one has reported seeing the parasite in the rectal mucosa before The method of infection seems fairly clear in his cases contamination of home-grown vegetables, especially of lettuces, by infected human excreta had served to provide the whipworm with hosts in three members of the family.

known men will vouch" During an Atlantic voyage Graham took nothing by mouth for five days but gave himself two gallons of sea-water daily by rectum He drank half a glass of water on the sixth day and some more on the seventh, but reported that this was not strictly necessary He claimed to have felt well and only slightly thirsty throughout Graham must have had an exceptional mucosa, for recent experimenters have failed to repeat his feat FOY, ALTMANN and KONDI[2] withheld all fluid from six volunteers of the South African Medical Corps for three days Three men served as controls while the other three had sea-water enemas It was found impossible to give more than 800 c cm of sea-water daily (four doses of 200 c cm) by rectum with any hope of its retention, but even this small quantity was more harmful than beneficial The subjective and objective symptoms of dehydration were much the same in the two groups, but there were great differences in the chloride conditions In the sea-water group the chloride concentrations in blood and urine and the total chloride excretion were greater than in the controls, showing that chloride had been absorbed The increased urine output more than counterbalanced the fluid absorbed, for the sea-water group lost more body-weight than the others Two of the sea-water group had lumbar pain An experiment on a single subject anonymously reported from America[3] supports these findings A young man was given sea-water enemas on the third day of a total fast, but each time he complained of colic and expelled fluid which was greater in quantity and more dilute than the sea-water given It seems then that, with possible individual variations, the rectum is no more selective in this way than the stomach

Yet there are plenty of aquatic mammals who spend their lives as in an open boat How do they manage? Their blood, it is true, is slightly more salt than ours, but it is still highly hypotonic compared with sea-water Seals in captivity, according to IRVING and others,[4] would drink fresh water greedily when they could get it but did not seem to drink sea-water By controlled feeding with herrings and by calculating the water loss from all sources—lungs, urine and fæces—they found that the account could be balanced from the water content and water of combustion of the food alone, and HOMER SMITH,[5] from observations on a seal periodically catheterised, agrees that only traces of sea-water are swallowed, even when the seal engulfs a fish under water SMITH is satisfied that the whale also obtains all its water from the microscopic marine organisms it eats, using its whale-bone comb as a filter from which it can lick off the solid matter when it has rejected the sea-water. LAURIE,[6] however, puts the whale's urinary chlorides at about 3%, compared with the average in man of about 1%, and KROGH[7] quotes an even higher concentration, so that the whale's kidney may do more than ours can to counterbalance a high chloride intake

What measures can the shipwrecked seaman take to eke out his fresh-water supplies? He loses fluid from the lungs, skin, urine and fæces He can minimise respiratory loss by reducing excretion to a minimum As regards skin loss, MELLANBY[8] recalls that many desert animals avoid desiccation by living in burrows in which the humidity of the air is high although the air outside is very dry The seaman can imitate them by erecting a tent for himself, or putting up his canvas hood if his boat has one, and keeping it soaked with sea-water, so that he lives in a saturated micro climate out of direct sunshine, while avoiding the exertion of bathing Urine and fæcal loss he can minimise by ensuring that his diet contains neither diuretics nor laxatives The diet should clearly be salt free, a high fat-carbohydrate ratio will produce most metabolic water per weight of foodstuff, but MELLANBY demonstrates that this is of little if any advantage One controversial suggestion that will no doubt be tested in the inquiries now being carried out is that the available water should be made isotonic by dilution 2 1 with sea-water, or even be made slightly hypertonic in hot climates where there will be an appreciable chloride loss from the skin It has yet to be shown, however, that this procedure is sound Another possibility worthy of inquiry is the value of vasopressin in ensuring maximal concentration of the urine, it has been shown[9] to produce a negative sodium and chloride balance in normal subjects, and in diabetes insipidus an injection of pitressin tannate in oil every day has proved as effective as injections of ordinary vasopressin every 2 or 4 hours[10] At any time, though, such speculations may be rendered superfluous by the production of a practical desalting apparatus, whether working by adsorption, electrolysis, distillation or chemical means

PSYCHIATRY AND GENERAL MEDICINE

THE London Hospital, which set up systematic lectures on the psychoneuroses some twenty years ago, has now appointed a psychiatrist on the staff, to work in the joint department of neurology and psychiatry, and the step will be welcomed by those who have striven for the recognition of psychiatry, in its modern form, as an integral part of clinical medicine The day is gone when the psychiatrist was only called in to decide when a man was insane, and when clinical instruction in the subject consisted of a few visits to an asylum and the viewing of some advanced cases of lunacy Psychiatry has now—after some resistance, we must admit—assimilated the teachings of psychopathology and applied them in the handling and treatment of patients who had hitherto been outside its activities A notable result of this development is to be seen in the Army psychiatric service, now organised in a way that fills with envy the few survivors of past battles and carried on by asylum-trained officers working in easy accord with others whose approach to the subject was, not so long ago, regarded by orthodox psychiatrists as a sort of burglarious entry The lion and the lamb have lain down together, and if the lion does devour the lamb it may be hoped that few will be disturbed by the happening thus metaphorically expressed, the provision of nourishment for the psychiatric lion may turn out to have been the proper function of the psychotherapeutic lamb The relationship of neuro period of treatment, but for none of these was the operation directly responsible 12 patients have required a subsequent thoracoplasty and in 5 more the operation is contemplated From the discussion it became clear that permanent closure of a cavity by suction drainage is rare (Monaldi claimed less than 20%) but reduction in size and temporary closure can be achieved in a large proportion of picked cases Sellors emphasised the importance of the supply bronchus, and so did Dr R J C Maxwell, who found in his series of patients at the Surrey County sanatorium that the prospect of a successful outcome varied inversely with the number of bronchi opening into the cavity When three or more bronchi entered the cavity, closure by suction drainage was impossible The operation improves the general condition of the patient by reducing toxæmia and reducing cough and sputum—it is, as Dr Peter Edwards said, the perfect cough mixture Closed suction drainage by reducing a distension cavity to reasonable proportions and by increasing the general health of the patient has proved a valuable, often indispensable preliminary to thoracoplasty Moreover, a more simple type of thoracoplasty may often suffice after preliminary drainage Nor is the method particularly risky, alarming hæmorrhage and infection of the chest wall are rare complications Suction drainage is still on trial but the results so far are encouraging

SLUMBUG

THE devastation of towns and cities by aerial bombardment has this gleam of compensation, that many of the areas destroyed were squalid and overcrowded When we rebuild we shall have an opportunity of eliminating that reproach to civilisation, the slum But this elimination is not inevitable or even easy, only by taking thought can we avert the evils of the past A very persistent and troublesome characteristic of the slum is the bed-bug The spread of the bug into new areas depresses the standard of hygiene and drives away more scrupulous householders The bug is therefore actually one cause of slums, as J W. Munro pointed out in the past A vigorous campaign against the bug is necessary to ensure better standards of urban life in the future Meanwhile a special bug problem has arisen as a result of the war The bug has invaded a great number of air-raid shelters and was becoming a serious problem when the air-raids on this country died down If frequent raids are made in the future, it is certain that this trouble will recrudesce Attempts to extirpate the bed-bug have in the past been handicapped by lack of precise knowledge of the bug and of the best insecticides During the years 1935–40, however a concerted attack on the problem has been made by various experts coördinated by the Bed-bug Infestation Committee of the Medical Research Council The council have now published a report[1] summarising the results of the investigations The research was planned to solve questions puzzling practical men and the new information in the report will be useful to all those having to deal with bug infestations In section one, P A Buxton and C G Johnson present a picture of the growth of bug populations under field conditions[2] The great merit of this work is that the experiments were planned with special reference to the actual status, it is surprising how much of the previous research on the bug was made under unnatural laboratory conditions In this latest work there is a real attempt to bridge the gap between precise but artificial work in the laboratory and observations on uncontrolled wild bug populations One of the most interesting things which emerge is the difficulty which a bug population has in maintaining itself in an unheated room At winter temperatures bugs will not feed and a great mortality ensues In heated bed-sitting rooms on the other hand the population growth of the summer months is maintained far into the winter These findings are borne out by the constitution of samples of bugs taken from rooms at different times of the year J W Munro and A B P Page are responsible for section 2 which deals with the chemical properties of bug insecticides Most of this relates to heavy naphtha, a relatively new insecticide, and to hydrogen cyanide fumigation The complex mixture of substances in heavy naphtha invited research to determine the active ingredients In the course of this work some interesting new principles of toxic action were discovered The experimental cyanide fumigations were planned to define safe and efficient limits for this important method S A Ashmore and A W McKenny Hughes in section 3 describe the practical details of heavy naphtha fumigation and give a specification of the material It is claimed that heavy naphtha combines efficiency with complete safety, certainly it has the great advantage in war-time of being home-produced and inexpensive W C Gunn stresses the importance of domestic hygiene in section 4 Unfortunately there are some people too ignorant or too lazy to carry out proper cleansing measures In stimulating and assisting such people health visitors and sanitary inspectors can achieve a great deal In section five, G R Cameron deals with the toxicity to man of insecticides used against the bed-bug This is often difficult to assess because some compounds do not produce symptoms at once but only after long periods of frequent small exposures Moreover it is unsound to rely on only one kind of animal to predict the effects on man, several species of mammal have to be used The report ends with special instructions for preventing or curing bug infestations in air-raid shelters and there is an extensive annotated bibliography compiled by J Smart

BREAKFAST WITH THE BORGIAS

POISONERS have flourished since man first discovered that some changes in the internal environment are more than the living organism will bear Nor has the law hesitated to make use of this peculiarity of protoplasm Dr G Roche Lynch, addressing the Medico-Legal Society as its retiring president on July 16, quoted an early Egyptian papyrus where "the penalty of the peach" showed prussic acid to be a recognised means of liquidating malefactors The Greeks of course, used hemlock and he reminds us that the word "toxic" derives from τοξος—the bow which discharged a poisoned arrow In medieval England poisoning was so repulsive to the legal mind however that the statutory punishment for the poisoner was to be boiled in oil—a highly unfair arrangement since the tests for deciding whether death was due to poisoning were far from satisfactory Thus it was believed that a poisoned body—and especially the heart—resisted fire more successfully than one in which death had been natural Apart from the requirements of murderers and the law, the chief demand for poisons is to be found among suicides The Registrar-General's figures show that men prefer strong acids, cyanides, opium and coal gas, women choose oxalic acid (possibly because it is also handy for cleaning straw hats), phosphorus, the barbiturates and disinfectants Between 1921 and 1938, however about two-thirds of British suicides were compassed with carbon monoxide, and the preference for this gas is increasing As non-poisonous disinfectants become commoner the deaths from carbolic acid and lysol are falling, poisoning by opiates has been much reduced by the Dangerous Drugs Act, and the sale of barbiturates is partly controlled by the Pharmacy and Poisons Act of 1933, though these drugs are, in Dr Roche Lynch's opinion, still too freely prescribed by doctors Aspirin poisoning is

Annotations

VITAMIN C FROM PARSLEY

WATERCRESS, usually looked upon as the best of the salad vegetables as a source of vitamin C, is far surpassed by parsley, for Morgan[1] has found an average of just short of 280 mg of ascorbic acid per 100 g in nine samples of parsley leaves gathered in Cambridge this spring, whereas Olliver gives 61 mg per 100 g as the average figure for watercress Morgan therefore advocates a much greater consumption of parsley and rightly says it is both an easy and a decorative crop to grow in the garden Moreover it is available all the year round, though it remains to be seen whether the vitamin content is as large in winter On Morgan's findings 60 mg of ascorbic acid—the optimal daily requirement for a 11 stone adult—would be contained in about ¾ oz of parsley, a large handful, but no one would suggest taking the whole of their vitamin in this form It will be best to eat the fresh leaves, either in a salad or sandwiches, though Morgan found no loss of vitamin from keeping them in water for two days Chopping with a sharp stainless steel knife reduces the ascorbic acid content by 20% Morgan gives a recipe for parsley lemonade An ounce of picked leaves are pressed down in a jug, ½ a pint of boiling water is poured on and allowed to stand for 2 minutes, and the whole is then squeezed through muslin or calico This produces a cloudy, lemon yellow infusion containing 40–56 mg of ascorbic acid (equivalent to the juice of an average orange) and tasting only slightly of parsley It can be flavoured with, for example, one of the lemon substitutes

NUFFIELD RESEARCH AT OXFORD

IN view of the founding of the new Nuffield chair in social medicine, it is timely to recall the other Nuffield foundations at Oxford The old observatory, with its perfect lines and bland windows, houses the Nuffield Institute of Medical Research where Prof J A Gunn, the director, carries on his research in pharmacology and Dr A E Barclay, Sir Joseph Barcroft and Dr K J Franklin are continuing their study of the circulation by X ray cinema Apart from the institute, four of the Nuffield research departments—medicine under Prof L J Witts, neurosurgery under Prof H W B Cairns, obstetrics and gynæcology under Prof J Chassar Moir and anæsthetics under Prof R R Macintosh—are associated with the Radcliffe Infirmary, the department of orthopædics, under Prof H J Seddon, is at the Wingfield Morris Hospital The departments of neurosurgery and of gynæcology and obstetrics occupy new blocks of buildings, attached to the infirmary, with good wards, theatres, offices and equipment Medicine anæsthetics and clinical biochemistry share temporary buildings for their laboratories and treat patients in pre existing wards and theatres of the Radcliffe Infirmary Hopes of new quarters have naturally been suspended by the war The department of neurosurgery is closely linked with the Services through the hospital at St Hugh's College and the combined research on head injuries, and the department of orthopædic surgery is acting as one of the special centres for the study of nerve injuries The work of the research departments has been much affected by other war time changes It was intended that they should serve as training grounds for experts capable of taking up appointments elsewhere, and in this respect they have more than fulfilled their obligations, for each department has released a large share of its personnel to the Services For young research teams (the departments were only started in 1937) this has been a heavy loss, and, owing to the decision of the university to extend the education of medical students to cover the clinical years, the departments have had to undertake teaching responsibilities unforeseen at the time of their foundation The principle that a university should undertake the training of students while maintaining research is, of course, an old and good one, but the double obligation has perhaps fallen rather hardly on these young departments, founded primarily for research alone The scheme for giving a complete clinical training at Oxford was begun as a war time measure, and may perhaps end with the war, on the other hand it is a plan of such promise that if it can be thoroughly developed many would wish it to survive Should it become permanent it seems that the position of the Nuffield departments will have to be considered afresh If they are to be pre eminently research departments, the research beams must be released from those more exacting aspects of teaching which could be delegated to a less specialised staff, to train experts, however, will remain a natural function of the departments and one which they will be ready enough to fulfil

SUCTION DRAINAGE OF TUBERCULOUS CAVITIES

THE distension type of tuberculous cavity in the lung has proved singularly resistant to collapse therapy The work of Cairyllos and his colleagues, extending over the last decade, has shown that these cavities depend on a check-valve mechanism in the supply bronchus, due either to kinking or to tuberculous disease The partial obstruction allows air to enter but prevents its exit, and so leads to the formation of a very large cavity Secretions collect in it and atelectatic lung tissue, capable of reinflation, forms the wall The insertion of needles and even tubes into such cavities is not novel, in England, Pearson[1] has studied cavity pressures by such methods for many years, but it is only recently that Monaldi and others in Italy have devised a method for the successful drainage of these cavities This closed suction method was discussed at a meeting of the Tuberculosis Association at Oxford on July 3 Mr T Holmes Sellors outlined the technique of the operation For success, the layers of the pleura must be adherent over the cavity to be drained If a space is found when a pneumothorax needle is introduced some air is injected followed later by a sclerosing solution such as auri et sodii thiosulphas (*BPC*), silver nitrate or the patient's own blood As soon as the layers are firmly fused the site of the cavity is determined by screening the patient in the exact position that he will occupy on the operating table, and the chosen point of entry marked The risk to the operator's hands is too great for the operation to be performed under the screen The chest wall is locally anæsthetised and a fine trocar and cannula are inserted into the cavity, the correct depth being ascertained by manometric readings The anterior approach is preferred and healthy lung tissue can be traversed without risk As soon as the cavity has been reached the trocar is withdrawn and a barium loaded catheter with multiple side eyes is threaded into the cavity and allowed to coil up within it The cannula is removed and the tube attached to a suction pump Suction is maintained at 3–5 mm Hg continuously from the first post-operative day onwards for weeks or months An apparatus for suction drainage easily composed of materials to hand by anyone who can use a soldering iron has been described in our columns by Mr Arthur Edmunds[2] The tube in the cavity is gradually withdrawn under serial X ray control Mr Sellors finds that in favourable cases the sputum and secretions become negative for tubercle bacilli, and at the finish the size of the residual cavity, which may have been reduced to a mere fistulous track, can be estimated radiographically by running in some opaque oil through the catheter Sellors's results in his first 41 cases are cavity completely closed in 6 cases, considerable reduction in the size of the cavity in 27, no appreciable diminution in size in 8 cases, 3 patients died during the

DIPHTHERIA IN INOCULATED PERSONS

B T J GLOVER
M D LPOOL, D P H
SENIOR ASSISTANT MEDICAL OFFICER OF LIVERPOOL

H D WRIGHT
D SC, M D EDIN, M R C P E
PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF LIVERPOOL

(Departments of Public Health and Bacteriology, Corporation and University of Liverpool)

INOCULATION against diphtheria has been undertaken in Liverpool since 1925 and the results have been followed with some care The dispersal of population and disturbances following the outbreak of war have made this supervision much less satisfactory, and it therefore seems worth while recording the results obtained up to the end of 1939 in persons inoculated before the end of 1938

TABLE I—PROPHYLACTICS USED

Prophylactic	Date	Dose	Interval
MT toxoid	Oct 1925–May 1932	3 × 1 c cm	1 week to Jan 1932, 2 weeks thereafter
Toxoid antitoxin mixture (TAM)	March 1932–Dec 1933	3 × 1 c cm	2 weeks
Formol toxoid (FT)	June 1933–Dec 1935	3 × 1 c cm	,,
Toxoid antitoxin floccules (TAF)	May 1932–Dec 1938	3 × 1 c cm	,,
Alum-precipitated toxoid (APT)	Nov 1935–July 1938 Aug 1938–Dec 1938	1 × 0 1, 1 × 0 5 c cm 1 × 0 1, 1 × 0 5 c cm	,, 1 month

Five prophylactics were used during the period under review (table I) The small number of persons inoculated with toxoid-antitoxin mixture (TAM) have not been considered further and a few who received various mixtures of prophylactics have also been neglected The number of persons of various ages inoculated with each of the prophylactics is given in table II, with the number so inoculated who were subsequently infected with diphtheria

TABLE II—NUMBER OF PERSONS OF DIFFERENT AGES INOCULATED WITH DIFFERENT PROPHYLACTICS AND PARTICULARS OF DIPHTHERIA INFECTIONS IN THESE PERSONS

Prophylactic	No of persons inoculated			Total	Infections			Typed			
	Age—0–4 yr	5–9 yr	10 yr +		Cases	Complications	Deaths	Total	*Gravis*	*Intermedius*	*Mitis*
MT	800	1300	1021	3121	36	5	6	9	4	3	2
TAF	3029	17115	5869	26013	206	10	3 + 1*	131	72	43	16
FT	1425	1700	0	3125	20	1	0	19	13	5	1
APT	5537	17182	7	22726	134	11	1	132	79	34	19
All	10791	37297	6897	54985	396	27	11	291	168	85	38

* This patient received 1 dose of MT, reacted strongly and was given 2 doses of TAF

TABLE III—AGE INCIDENCE OF INFECTIONS IN INOCULATED PERSONS

Prophylactic	Age					Total
	Not known	0–4	5–9	10–14	15 +	
MT	0	6	17	12	1	36
TAF	4	2	118	69	13	206
FT	1	0	19	0	0	20
APT	0	12	119	3	0	134
	5	20	273	84	14	396
Fatal cases	0	3	6	2	0	11

In the infections of inoculated persons the percentage incidence of the various types was gravis 57 7, intermedius 29 2, mitis 13 1, as compared with the average for all cases in Liverpool in the period 1937–39 · gravis 45, intermedius 20 8 and mitis 34 2 The differences are statistically significant (D/SE gravis 4 3, intermedius 3 6, mitis 8 1) On the whole the cases are reported as very mild, but 27 showed various complications of toxic origin and there were 11 deaths The age-incidence of the infections in inoculated persons is as shown in table III

The intervals between completion of inoculation and infection in these cases are recorded in table IV No case which occurred within 12 weeks of inoculation has been included, since immunisation is unlikely to be adequate within this period

TABLE IV—INTERVALS BETWEEN INOCULATION AND INFECTION

Prophylactic	Interval between inoculation and infection (weeks)						Total
	Not known	12–49	50–99	100–199	200–299	300 +	
MT	0	8	3	15	7	3	36
TAF	*1*	*32*	*49*	*77*	*38*	*9*	*206*
FT	0	4	4	10	2	0	20
APT	1	50	53	30	0	0	134
	2	94	109	132	47	12	396
Fatal cases	0	2	2	4	2	1	11

Particulars of the fatal cases are given in table V

TABLE V—FATAL CASES OF DIPHTHERIA IN IMMUNISED PERSONS

Case	Date	Age (yr)	Prophylactic	Interval (wks)	Organism	Cause of death
1	1932	2	MT	30	Virulent	Circulatory

DISCUSSION

The figures here presented do little more than place on record the experience of inoculated persons in the very heavily infected Liverpool area No Schick tests were done after inoculation and so these figures relate merely to persons who received one or other of the courses of inoculation recommended Large numbers of figures have been published from time to time as to the effect of such courses on the response to the Schick test or the antitoxin content of the blood, but few seem to be available on what really matters—the subsequent history of such children in relation to diphtheria infection By most persons the claim for complete immunity has of late been abandoned In this city it has been calculated[1] that the case-rate for uninoculated persons under 10 years of age for the years 1933–39 was 11 3 per 1000 per annum, while for those inoculated with different prophylactics it ranged from 1 5 to 3 Another interesting fact revealed in the same table is that in persons above the age of 10 years the diphtheria-rate is much the same in the inoculated as in the uninoculated

No doubt the diagnosis of some of these cases in inoculated persons would be open to question, but that also applies to many other cases of diphtheria What is clear is that there has been a not inconsiderable number of deaths among these patients The predominance of gravis and intermedius infections is well-marked and the risk of toxæmia correspondingly high, and in all fatal cases so far examined the infection has been due to one or other of these The list of deaths is, in our view, longer mounting, in spite of the quantity that must be taken; between 1936 and 1938 it accounted for 101 of 271 deaths from narcotic poisoning. Nicotine, used for fumigation by gardeners, is becoming popular with suicides; the lethal dose is minute and the action rapid. Strychnine is being given up though a few die-hards still swear by it. The ban on its sale for destroying vermin has been suspended during the war at the request of the farmers; less cruel methods are available, and Dr Roche Lynch hopes its use will be restricted again as soon as possible. Statistics of homicidal poisoning—for reasons beyond the control of the Registrar-General—are inaccurate. Probably only a proportion of murders by poison come to light. Dr Roche Lynch recalled that out of a series of 24 murders by poison, 8 were only discovered by exhumation, and that many poisoners have killed more than one person. The more cautious ones probably escape detection, but those who are apprehended show a strongly conservative spirit in their choice of drug. Arsenic has always been a favourite because of its small bulk, but large doses are sometimes vomited too soon to cause death, and several doses are often necessary. Opium can still be obtained in spite of legal safeguards, and Nurse Waddingham saved up a quantity which had been prescribed for dying patients under her care. Dr Roche Lynch holds that it is the duty of the doctor in charge of the case to take back any potent drugs from the nurse or family if the patient dies. Weed killer and industrial poisons like cyanide can be acquired fairly easily but attempts by a layman to buy an unusual poison are readily traced, and this limits the murderer's choice. A diagnosis of poisoning is seldom easy; sudden acute illness, he said, in a person in good health or stationary bad health is suspicious, and so is a sudden atypical change of symptoms. It is always worth noting if the patient complains of a change in the taste of food, drink or medicine. Bacterial or accidental food-poisoning usually affects all or nearly all who share in the food, whereas the murderer chooses his occasion to poison one victim. Recovery from poisoning is surprisingly rapid compared with that from most natural illnesses. If the doctor suspects poisoning while the patient is alive he is in a difficult position, but he can approach the Home Office with a request for analysis of a specimen. If he cannot get the patient into hospital he should employ a trustworthy nurse and confide in her so that she can be on her guard, and prepare all food and drink for the patient herself.

MEASURING IMMUNITY TO SMALLPOX

The smallpox outbreak in Glasgow has brought home to us how little is known about the degree and duration of resistance which vaccinia produces to this dread disease. In face of an outbreak of diphtheria, the Schick test can be used to separate the susceptibles who need protection from the immunes who can be left alone. But when smallpox appears all likely and many unlikely contacts are vaccinated, and those who do not "take" are left with the uncomfortable feeling that they may or may not be immune. A method that would measure resistance to smallpox would therefore be a great boon. When Hirst[1] published his discovery of the agglutination of chick red blood corpuscles by the influenza virus, it was natural to inquire whether other viruses had a similar property. In the course of such an inquiry, Nagler[2] found that vaccinia virus also had an agglutinating action on fowl red cells, and that, as was the case with influenza virus, the agglutination could be specifically inhibited by anti-vaccinia serum. For the test he used vaccinia virus grown on chick chorioallantoic membrane, which agglutinated a 2% suspension of fowl red cells to a dilution of 1/256; virus grown in the yolk-sac was ineffective, and the cells of certain birds, particularly older birds, reacted poorly. Using the serum of an immunised rabbit as standard, Nagler showed that vaccination with egg-virus raised the titre of a patient's serum from 0·025 unit before vaccination to 0·05 unit at 12 days and 0·4 unit at 21 days and 28 days after vaccination. A test like this which can measure the degree of resistance obviously has a variety of uses. It can assess the relative antigenic value of egg, calf or otherwise produced virus, discover whether two or more insertions are more effective than one, and perhaps determine the potency of different virus preparations. But its primary use will be to decide whether or not to vaccinate when smallpox is about.

SWAPPING PATIENTS

Doctors are scarce and so is petrol, and it is no longer proper for practitioners to travel far afield to see patients who could well be visited by a doctor who lives nearer to them. Accordingly insurance patients are being re-allocated, with the consent of the doctors concerned, for the duration of the war "so as to secure economy in the use of civilian medical man-power." But there is some doubt whether under the protection of practices scheme a doctor has the right to transfer to another practitioner patients assigned to him by a colleague absent on war service, without written consent—which in these days of disturbed communications may be impossible to obtain. To meet this difficulty the Ministry of Health has issued an enabling regulation investing the deputy with the rights of a principal over these temporary patients and no longer requiring him to insert the name of the absent practitioner on any certificate or document issued in respect of his patients. Presumably the absent practitioner will no longer be responsible for the acts or omissions of his deputy. The BMA have made similar proposals—popularly known as the five mile limit plan—for the temporary reallocation of private patients, but the experienced family doctor is not finding it easy to break the ties of a lifetime at the call of a measuring tape.

UNITED SCIENTISTS

At a reception on July 23, given by the Royal Society of Medicine and the British Council for medical and scientific representatives of the united nations, Dr A. M. H. Gray made his large and cosmopolitan body of guests feel the warmth of their welcome. Sir Henry Dale, with his wide contacts in science at home and abroad, was able to give perspective to the hopes and aims of all those present, and Lord Snell spoke of the better uses to which we may hope to put science when it takes off the harness of war. Till then, as the professorial staff of the Gorky All Union Institute of Experimental Medicine declared in a telegram of greetings received the same day by the Physiological Society, "We must pool our creative desires to form a fund of scientific achievements" which will help us all to speedy victory. In his reply Prof. A. V. Hill looked forward to a lasting brotherhood in scientific service.

A MISWORDED ADVERTISEMENT.—Several correspondents have expressed surprise at an advertisement for a locum tenens in our issue of July 18 containing the proviso "Aliens and Jews need not apply." The intention of the advertiser was to signify that owing to the nature of the practice a doctor of British nationality was essential. We deeply regret that through an oversight the advertisement was allowed to appear in such form.

" A mass X-ray examination of 98·4% of the people in Stuttgart resulted in 7500 being suspected of tuberculous infection. A further examination of these confirmed the diagnosis in 3444 cases (i.e., 0·76% of the population), 737 had a progressive tuberculosis requiring treatment, of which they were ignorant, and of these 182 cases were open."—From *Bodensee* for April 6, 1942.

[2] Nagler, F. P. O. *Med. J. Aust.* 1942, 1, 281.

jump up and lick my face. So I smile, and with a courtly little bow invite him to precede me. “Oh, thank you thank you,” he pipes and squeezes by. His voice is gummy from long disuse. Aha he has found an old crony and is eagerly sidling along the pew towards him. That's good. I always seem to collect funny inarticulate people around me and there they are apt to hang for hours and hours. But I'm glad I risked being nice to the little grey-haired man. My little moment of Goodness. Now whom shall I sit next? This coloured gentleman doesn't look too communicative. He'll do.

Why does one come to conferences? I was looking forward to meeting Francis Flute the sanatorium superintendent, and Snug the thoracic surgeon but they haven't turned up. I ought to have made sure first. I survey the rest of us filing in. More than half have their eyebrows fully raised and a good third have their mouths ajar. My God we look positively frightening in the mass. Come come I'm not usually so misanthropic. Why is it? Those baked beans, unless I'm mistaken. The chairman calls on the speaker Bully Bottom the Weaver of Plausible Non-Sequiturs. No that's a bit unkind. Let us say the Voice That Breathed O'er Brompton. We stamp our feet. The blinds rattle down at a touch of a switch. We snuggle down for a little light hypnosis as the dazzling rectangle splashes on to the screen. ‘The first slide shows ’ and all our eyes converge on the pointer's tip and follow its wavy course like the hen's along the chalk line. The fug deepens. Click, a second slide. Well *I* can't see any difference. The coloured gentleman is breathing very deeply. Bit of yoga to pass the time? Tobacco smoke swirls in the lantern's beam. The pointer relentlessly collects our eyes and shows us what differences we ought to see. Of course I see now. All the same I wish the two slides could be shown side by side. I can't help feeling there's a catch in it somewhere. What's he talking about now? Contraceptive collapse? It CAN'T be. Oh contraselective collapse. He shouldn't talk with his mouth full. More murky slides. If ever I address the mob I'll show my slides demonstrating the marvellous effect of my patent cure in the reverse order. They would never notice. Not they. He's finished. We stamp our feet. Now for a cup of tea and two biscuits, price fourpence. No damn, there's still the discussion. I do want my tea. Somebody gets on his feet and talks. He hasn't been listening either but that doesn't deter him. He seems to be extolling green vegetables. I must say old Bottom takes these irrelevancies very well. Just goes on lighting his pipe. His answers to the points raised are statesmanlike and noncommittal. In fact they don't mean a thing. Now for some tea. Quick. I must edge away from old Bottom who seems to be making straight for me. Too late. Oh what am I to say? What *am* I to say? ‘Those seats are so damned hard I haven't had a wink of sleep.’ He grins satisfied, and I breathe again. I have had my little moment of Truth and got away with it.

* * *

Sometimes after a long afternoon round I come in for a late tea and listen to the 6 o'clock news. However gripping, if I shut my eyes the same sequence occurs. I feel I can listen just as intelligently, then I hear the words and don't get the picture then I turn the noise into a pattern, and then disregard it. But these layers of consciousness don't end here—there are hundreds of them. One of the top ones is the parody layer where what you have just been doing or seeing is made grotesque. There are the childhood layers of sentient glamour, the feeling of being in the shrubbery as it is getting dark, the adventurous feeling of a packet of sandwiches and a whole enormous day in front of one. Then there are the adolescent layers, the one of prowess where one plays rugger sublimely, dodges, swerves, feints and finally dives over the line for a glorious try (the Freudians would say this is the memory of the spermatozoon's struggle to reach the ovum). Some of these layers are unpleasant—the examination dream of ignorance and inarticulateness, or the badly dressed dream in a room full of fashion-plates. There are several debating layers, where one argues cleverly and interminably, but not in words or about anything in particular. I don't know whether the personal layers are all together or scattered among the other strata, but there is one for each person whom one has known intimately, especially those people in whose presence one was completely happy without talking. Du Maurier's “Peter Ibbetson” deals with one of these personal layers. By trying to remember what went before and after each dream and sometimes succeeding, one might be able to sketch out the various strata. Would one find it was chronological, the older memories deeper down? Or utilitarian, dreams being Nature's escapist literature, that type being supplied which is most needed, like the rejuvenating childhood memories in senility? Sometimes one flits past many layers—has a glimpse of a dream of a few nights ago, a word or two with one's grandmother, and finally settles in some deep stratum of amœboid content. I by no means rule out the possibility of telepathy playing some part in fixing a dream at a certain stratum. This geology of dreams would form a useful subject for a team of investigators, not psychologists, they know too much and have preconceived notions on the subject, but people like myself, village doctors. We might even find a drug which would fix one's dream at a particular stratum. “You want to dream about——? How long ago was that? Twenty-two years. Let's see (consulting the sliding scale), that'll be tri-bozo-barbiturate.” At any rate I have found that the small amount of morphia in tinct. camph. co., or the codeine in two ‘Veganins’ give me coloured childhood dreams while aspirin dreams have a black-and-white, metallic, practical quality.

* * *

George the blacksmith who periodically shoes my mare is undoubtedly the best-loved man in the village, largely because he unobtrusively exhibits most of the Christian virtues. He is perennially cheerful and friendly, helpful and merry-eyed. He enjoys his pint of ale and spoils the evacuated children who are always in and out of his shop and never rebuked no matter how much they get in his way or tamper with his tools. He and I have frequent talks about the bad times by which we mean no more nor less than the modern practice of tarring road-surfaces which makes them slippery as glass under a horse's feet. In the course of our conversations George frequently quotes one Perkins whom he thinks I know; as a matter of fact I don't and haven't the courage to say so at this late date. Perkins, it seems, is a sort of super-horsemaster, an oracle who is not, however, regarded by George as necessarily infallible. Thus, although “Perkins always says” is a frequent opening remark, it is often followed by “but I thinks meself.” George and I thought that one frost-nail tacked into each shoe might make the mare less liable to slip. We tried it and we were right. “Now Perkins 'ud 'a putt een a larger nail,” said George, “but I likes these yur small wans.” So do I. Indeed, I'd back George's opinion against Perkins's every time.

* * *

He is 75, still in active practice and keenly interested in the future of medicine. He is a general practitioner-surgeon of considerable local repute and still enjoys tackling emergencies on the kitchen table. “One day last winter,” he said, “I was asked by a neighbouring doctor to see a big fat farmer with an acute abdomen. When I got there all I could see was a great mountain of belly rigid as a board. We fixed up some planks on a couple of trestles, the doctor gave the dope and the only other help we had was a gamp. I don't like gamps, they aren't clean, so I herded this one into a corner away from my instruments where she could do no harm. I made my incision, turned round to pick up a pair of Spencer Wells and caught my head the most almighty crack on a low beam which nearly put me out. However, I recovered and for the rest of the operation remembered to bend double each time I turned round to pick up another instrument. I didn't do too much. I put in a tube and got out. He did all right. Just as I was sewing up I happened to look out of the window and there I saw old X (another doctor in the neighbourhood) hunting his hounds across the field at the back of the house and blest if they didn't kill there. I went out to have a word with X. ‘And what the hell are you up to?’ I asked. ‘Just killed a fox,’ he said, ‘and what have you been doing?’ ‘Just saved a man's life,’ I said. ‘Which of us has done the best morning's work?’ ‘I dunno,’ he said. ‘Nor do I,’ said I.” Nor do I.

than it should be. It is noteworthy that 6 of the 11 deaths recorded occurred in persons inoculated with the prophylactic MT toxoid. This was one of the earlier forms of formol toxoid, and was found early in 1932 to be unsatisfactory on other grounds, particularly because it gave a very low Schick-conversion rate in a series examined. It seems clear therefore that some of these failures may be attributed to the use of an unsatisfactory prophylactic. The last 2 cases mentioned in table V are of interest in that they were sisters and had been inoculated with different prophylactics; they might well be an instance of a strain of human being difficult to immunise, for the attacks were of a most fulminating type, and rapidly fatal. As mentioned above, no Schick tests were done in any of these cases and it is highly probable that some of the failures in immunisation would have been demonstrated by such a test. Excluding the group of inoculations with MT toxoid it seems that one uncontrolled series of inoculations has reduced the risk of infection with diphtheria in this heavily infected environment to somewhere about $\frac{1}{10}$ of that of the uninoculated person; the risk of death is not entirely eliminated but is reduced to something like the same extent, for the case-fatality in this small series is 1·39% (excluding MT cases) while that of the intermedius cases as a whole in Liverpool is about 10% and of the gravis cases 6·5%.

The response of the people of this city to the offer of inoculation free of cost has been most disappointing. As a result of efforts up to the end of 1939 some 60,947 persons had been inoculated.[2] Of these, 4976 were at that date less than 5 years old, 26,089 aged 5–9 and 29,852 aged 10 and over. On the basis of the 1931 census figures, this means that 6% of the children under 5 years were inoculated and 31% of those aged 5–9 years. These proportions would be expected to be inadequate to affect the incidence of diphtheria significantly, and there has in fact been no evidence of any decline of diphtheria incidence in the city.

SUMMARY

In Liverpool during the years 1932–1939 there were 396 cases of diphtheria with 11 deaths in 54,985 inoculated persons; 6 of the 11 deaths occurred in persons inoculated with what appears, on other grounds, to have been an unsatisfactory prophylactic.

MEDICINE AND THE LAW

Mistake of a Decimal

A FATAL misunderstanding as to the strength of an anæsthetic led to a claim for damages against the doctor who was acting as honorary anæsthetist to the hospital where the operation was performed. Mr Justice Lewis, at the recent Hampshire Assizes held that the mistake did not amount to negligence. Mr Alfred Fussell was suing Dr J R J Beddard, alleging that he had been negligent in administering an overdose. The plaintiff's case was that, Dr Beddard and the surgeon having decided to use 'Decicain,' Dr Beddard had asked the hospital sister for a "one per cent solution"; the drug was in a bottle labelled "one per cent solution"; the sister, it was said, held up the bottle with the words "One per cent solution—is that right?" Dr Beddard gave evidence that he had decided to use a 0·1 per cent solution and that he asked the sister for a "point one per cent solution." The judge, while expressing sympathy with the husband of the dead woman, found himself unable to treat the misunderstanding as establishing negligence on the anæsthetist's part. The sister had the highest qualifications and everyone was accustomed to rely on her. Nor did he think the sister was to blame in the sense of being negligent in law. Judgment having been given for Dr Beddard with costs, the latter's counsel intimated that the defence would not ask for costs—a sympathetic course which the judge approved.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—At a meeting of the college held on July 21, with Dr Charles McNeil, the president, in the chair, Dr William George Clark (Edinburgh) was elected to the fellowship.

In England Now

A Running Commentary by Peripatetic Correspondents

I AM rather bitter about all this medical planning mainly because my own pet scheme of country instead of slum hospitals is obviously getting the worst of it. My only consolation is that I have the support of one of our most eminent hospital architects. Frankly, I have not yet heard a single sound reason against the country hospital.

It would be inconvenient for Harley Street? Possibly, but having been so inconvenient to everyone else for so long it is time Harley Street gave way to the convenience of the profession as a whole as well as patients. No one suggests that each hospital should not have a town centre for the treatment of outpatients and local emergencies, and in this centre the consultants could have their consulting-rooms, a move which would do them a world of good since it would stop the Harley Street ramp once and for all; a genuine consultant would possess an address which could not be acquired merely by being able to afford the rent. The advantage of cutting overhead expenses and of living in comfort rather than ostentatious discomfort is also not to be overlooked.

Students would not like it? How many medical schools have ever consulted their students on this point? I am tired of the fashion of condemning students when their views do not coincide with those of authority and using them for propaganda when it suits authority's purpose. Students are like children (and monkeys) in their suggestibility, and if led aright can be persuaded to support almost any scheme that is not wholly irrational. I suspect that the more thoughtful of our students are in favour of country hospitals; the vast bulk (i e, the unthinking section) have no views on the subject and would be equally happy in country or town, but when their teachers come down dogmatically on the side of the town hospital they automatically accept this view as their own.

Patients would not like it? Says you. Of course they are going to dislike anything that is new and put forward in an apologetic way. But our country hospitals are not going to be at the back o' beyond. They will be within easy access of London; they will be near either a railway station or a bus route, or a special 'bus service will be run from the nearest railway station on visiting days and there will be a hospital brake to fetch the relatives of dangerously ill patients at any time of the day or night. Extra expense? Negligible compared with the total cost of the hospital and could well be met out of a fraction of the money saved by rebuilding the hospital on a country site instead of in the centre of a town.

No, I refuse to believe that this vitally important question has been tackled impartially. Our honorary staffs (most of them at least) have approached it with preconceived notions. I challenge anyone to produce an iota of evidence that the sick person will not recover quicker and more surely in rural surroundings with ample fresh air, the maximum of sunshine and at least a modicum of natural beauty around him.

* * *

Why does one come to conferences? That lunch was calculated to make one downhearted and flatulent for the afternoon. I suppose we'd better be getting back to the lecture-theatre. The university drowses in heavy sunlight. The distant river sparkles invitingly. We pass two white clad girls playing tennis. Indifferent tennis, but the farther one moves like a Baronova. I'd like to sprawl under that tree and just watch her through half-closed eyes. I know she is going to haunt me for the rest of the afternoon. What sadness! Well, at any rate I have had my little moment of Beauty.

We leave the sunlight and swarm through dim chilly corridors. This place has the "thrilling-sweet and rotten" smell of a physiology lab, where alcoholic libations are poured out to the wrong gods. As I approach the swing-doors into the theatre I almost collide with that timid little man with the grey hair, who doesn't seem to have anyone to talk to and looks as if he wishes he had. I'd like to pat him over the shoulders and say, "Good old boy, then," but I'm afraid he might more than one occasion he had referred to the lack of suitable personnel both for the number of tribunals required and for the additional work which would fall upon his department The position in this respect is daily becoming more difficult, and the necessary staff could be obtained only by diverting to this ork persons at present engaged upon, or available for, work of mediate national importance

Consideration has also been given by the Government to the ggestion made by Mr S Silverman that pensions appeals ould be heard in the county courts, but, apart from the fficulty which the judges would have in undertaking this rious addition to their already heavy labours, the suggestion d not find favour with any of the bodies consulted as representing the interests of the persons concerned Sir W omersley had discussed it not only with his central dvisory committee, but also with the British Legion in ngland and Scotland and with the Trades Union Congress on ehalf of civilian claimants to whom a right of appeal would o doubt be extended Each of these bodies expressed a strong reference for the proposal to wait until it is possible to set up ibunals on the old lines

He was taking full advantage of the arrangement under which ases where there is serious doubt or difficulty on a medical uestion can be referred to an independent expert nominated y the president of one of the Royal Colleges In no case had e rejected the opinion expressed to him by one of these experts —Sir I Fraser Since the Minister cannot go the whole way, ill he not meet the demand in this House and in the country o the extent of placing these medical referees under the pay nd direction of the Lord Chancellor instead of their being nder his pay and direction ?—Sir W Womersley The edical referees are entirely independent of my department nd are under no pressure from me I do not think any lternative system to that of asking the presidents of the Royal olleges to make these nominations would be more satisfactory —Sir I Fraser Is it not a fact that, whereas the residents of the Royal Colleges of Surgeons and Physicians ominate these medical men, it is the Minister who takes the xecutive action of appointing them, and it is he who pays hem ?—Sir W Womersley I accept the nominations of the two presidents without question I do not ask them to send someone else, I accept whatever nominations are made These independent medical referees are entirely independent of my department

M R C Report on Silicosis

Mr James Griffiths asked the Minister of Fuel and Power if he could indicate the steps he proposed to take to implement the recommendations made by the Medical Research Council's committee on silicosis among coalminers —Mr T Smith replied As regards the improvement and wider application of preventive measures at the mines chiefly affected, which are in South Wales, the Minister has made proposals to the Monmouthshire and South Wales Coal Owners' Association and the South Wales Miners' Federation, which they have promptly accepted, and these are now being put into effect They involve the appointment by each association of a small committee to work and take action in collaboration with the two divisional inspectors of mines along the lines of procedure which are already being followed with good results in the anthracite area The extension of rights of workmen's compensation is a matter for the Home Secretary and his proposals will be communicated to the two sides of the industry before action is taken Mr Smith added that the M R C report proposed to alter the word "silicosis" to "pneumonoconiosis," and therefore there would be some old cases to which consideration would be given

Treatment of Tuberculosis

Sir Ernest Graham Little asked the Minister of Health whether he was aware that while the increased incidence of tuberculosis in females of the age group 15–25 was maintained, there was a sharp rise in two new categories—children under 5 and inmates of mental hospitals, whether he could now report what suggestions the Medical Research Council had made to explain the rise in the first category, and whether he had any explanation of the rise in the two new categories cited —Mr E Brown replied The points referred to will be dealt with in the report on the inquiry made by the Medical Research Council, which I am expecting to receive shortly

Dental Treatment for Young People

Mr K. M Lindsay asked the President of the Board of Education whether he would encourage local-education authorities to provide continued dental treatment for young people who have been regularly inspected and treated while at school and who now belonged to youth organisations —Mr R A Butler It is open to doubt whether local education authorities have power to provide dental treatment for young people who have left school and belong to youth organisations I realise the importance of this matter, but am bound to say that the shortage of dental officers, due to the demands of the Services, would make a general extension of the school dental service impossible at present —Mr Lindsay Will the Minister look at the scheme at Cambridge and at Guildford, where they are in fact putting this into practice ? —Mr Butler That is not under the powers which I would like to see but which do not exist It is under other powers

Vaccination

Sir Waldron Smithers asked the Minister of Health whether, in view of recent developments, he would take the necessary powers to make vaccination against smallpox and injections against other infectious and epidemic diseases compulsory —Mr E Brown replied I am advised that recent occurrences have not afforded any justification for such a change of policy as is suggested, but I shall continue to do all in my power to encourage immunisation against certain infectious diseases, either as a routine or when special circumstances call for such action

National Bread

Sir E Graham-Little asked the parliamentary secretary to the Ministry of Food (1) whether he was aware that the Lambeth borough council had asked to be relieved of their duties as food and drugs authority under the Food and Drugs Act, 1938, in so far as national bread and national wheatmeal were concerned, in consequence of the persistent refusal of the Ministry of Food to furnish a specification of national bread requiring a standard indicating maximum fibre content, minimum vitamin B_1 content and minimum oil content, in the absence of which the council found it impossible to state a legal case before a court, and whether he would amend the specification accordingly, and (2) what arrangements were in existence for testing whether the flour as it came from the mill was in accord with the specification laid down in S R & O 451, 1942, whether testing is carried out by officers independent of the milling industry, what punitive measures are taken when the flour is found not to comply with the specification, whether any definite proportion of the wheat germ is required to be incorporated in bread sold as national bread, and what is the average proportion of germ actually supplied —Mr W Mabane replied I am not aware of the circumstance mentioned in the first question The answer to the last part of that question is no As regards the second question, detailed particulars of the weekly production of flour mills in the United Kingdom are checked by my department to ensure that 85% extraction is being obtained in the milling of national flour Samples of national flour are drawn by mill inspectors employed by my department on all visits to mills These samples, which are drawn from bulk stocks, are sent to the laboratories of the Research Association of British Flour Millers at St Albans which, for the period of the war, are being used by my department, and where examination of flour and bread samples is made by one of the Ministry's scientific advisers Non compliance with the specification would be an offence against the Defence (General) Regulations and as such punishable by imprisonment or fine or both In the event of any infringement, the usual enforcement procedure would be applied In so far as the fourth and fifth parts of the second question are concerned, I would refer to the definition of national wheatmeal contained in S R & O No 451, 1942 The average proportion of germ in national bread cannot be stated precisely, but it is the maximum having regard to the technical considerations involved

Rank of Recalled RAMC Officers

Sir Alfred Knox asked the Secretary of State for War whether it was his intention that medical men who served in the last war in the rank of lieutenant or captain, Royal Army Medical Corps, should now be called up at the age of 41 to 46 years and posted to serve under youths of 25 to 30 years of age, who only received their medical degrees a few months ago —Sir James Grigg replied Medical men called up for service who held commissions in the RAMC for a year in the last year are gazetted captain from the date of joining Few RAMC officers under 30 are commanding units, and these are in all cases field force units with active duties, to which it is not intended to post the 41–46 year old officers

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS M P

WHEN Mr Ernest Bevin opened the debate on the administration of the Factories Acts last week he not only surveyed the present conditions and the improvements which have been introduced in war-time but hoped they would continue in peace-time, and be "of lasting benefit to the community" Mr Bevin is thinking of the structure of postwar industry, "nearly everything," he said, "which has been done [to promote the war effort] can be continued to the great advantage of peace-time industry" The main points of the speech were (1) the assumption by the Government of greater responsibility for the welfare of the worker, (2) communal feeding in factories and (3) the development and intensification of medical supervision and nursing services in the factory It was necessary the Minister said, to have government responsibility for welfare (and this would apply to the other points) because "we must not have a kind of industrial feudalism growing up in war" To the communal feeding organisation, this time by factory plus mobile canteens, Mr Bevin attributed the return to work in 14 days of 77,000 people out of 80,000 blitzed in Coventry and the restoration of full-shift work at Liverpool docks, after blitzing, in 3 days He wants factory canteens to be permanent

One of the main functions of the Factory Department, said the Minister, is the prevention of injury and of bad health There has been an increase in the accident-rate during war "owing to the very large recruitment of inexperienced workers" and there has been an expansion of the more dangerous industries But by giving close and continuous attention to all problems of skin disease—the Minister was referring to industrial dermatitis—the percentage rate is low, almost below the normal The House was told that many employers looked with great disfavour on the introduction of the works doctor but nearly all those who have introduced doctors will now admit it was a wise step to take

Absenteeism has been reduced, said Mr Bevin, "owing to the fact that a doctor and a nurse are on the job", and "the cooperation between the works doctor and the general practitioner has shortened illness enormously and in cases of accident it has meant quick attention" The works doctor has been of great service in organising first-aid arrangements and keeping them efficient, in looking after workers exposed to special risks, and in attending to the special problems affecting juveniles and women and "their cooperation with the private doctors and local health services has made the general service more readily available" Mr Bevin said that whole-time doctors have increased from 35 to 150 during the last two years This is a small number, and the suggestion made later in the debate that more retired and semi-retired men and more women should be employed merits consideration As also the suggestion that the panel doctor attending workers should be asked to take on factory duties where possible The Minister could not resist saying whimsically that if there were enough doctors for every little works it might perhaps be bad for us "We must not have too many doctors if we are to survive", on which Dr Haden Guest interjected that he hoped it would not be necessary to report the Minister to the BMA and Mr Bevin rejoined that his union was nearly as good as my honourable friend's The number of part-time works doctors has increased from 70 to 550 and the ministry have sought to expand the factory nursing service as rapidly as possible

Hours of work is a vexatious problem and Mr Bevin admitted that after Dunkirk there was for a time a strain on the Factories Acts administration that might have led to a breakdown Happily a check was imposed though he had been forced to permit things which were distasteful to him, such as agreeing to let young people work 60 hours in the week But now our man-power has been mobilised to such an extent as to justify the Minister in tightening things up at an early date He is now taking steps to prevent the employment of young nomads in the building trades—which for the first time have been brought under the factory department—and the special order allowing long hours of work in the cotton trade is to end with August Registration of young people should help us to give our young workers a better deal in the future

Later in the debate, Sir Geoffrey Shakespeare, chairman of the Medical Priorities Committee, stated, in answer to a question by a medical MP, that he had had consultations with Mr Bevin on the question of increasing the supply of doctors for factory work Mr Ellis Smith, speaking for the Labour Party, laid special emphasis on the need for the establishment of rehabilitation centres, and referred to a visit he had paid to that at Mansfield, established for the benefit of coalminers He asked for the working out of a national comprehensive scheme of rehabilitation as soon as possible

Despite the Minister's statement on the fall of absenteeism, Mr Simmonds, a Conservative member for one of the Birmingham divisions, purported to show that there had been an increase of absenteeism in June This increase Mr Simmonds, who is himself an employer, ascribed in part to medical men not being "as careful as they ought to be" in issuing certificates for absence, he proposed that the Minister should go very carefully into the matter with the medical authorities Another Birmingham employer raised the same point against doctors and read a number of certificates which he alleged were unsatisfactory On challenge a medical member offered to read the documents, if sent to him, and give his considered opinion In winding up the debate the Parliamentary Secretary to the Ministry (Mr Tomlinson) had not time to deal with these medical charges except that it seemed possible one of the certificates referred to was "a sort of forgery" While this question of certification will no doubt be explored, the medical conditions are good, absenteeism is declining, and health organisation will continue to improve

QUESTION TIME

Health in Occupied Europe

Mr Dingle Foot, parliamentary secretary to the Ministry of Economic Warfare, informed Mr Edmund Harvey that the worst conditions in German controlled Europe continued to prevail in Greece, in some parts of Poland and in occupied Russia There could be no doubt that deaths from starvation had occurred in these territories In the Greek cities, however, there had been an improvement, as a result of the shipments organised by the Allied governments The situation was not comparable in the other occupied countries, although it was broadly true to say that the urban populations were living at a level which was below, and in some areas substantially below, peace time standards Shortages of meat and fats were specially marked in the urban districts of Belgium and France The standards of public health did not appear to have been seriously affected in most other European countries But in Belgium and France there had been an increase, during the past two years, in the incidence of certain diseases, notably pneumonia and tuberculosis The insufficiency of the diet was no doubt one of the principal causes of this increase By agreement with H M Government purchases inside the blockade area were still being made for the benefit of Allied peoples Accordingly, over the last 13 months the Belgian government had made purchases of indigenous Portuguese foodstuffs, which had been sent to Belgium We had also made it clear that we would welcome the continuance and expansion of the scheme under which Belgian children whose health had suffered, were sent to Switzerland, and we had always been willing to grant additional navicerts to the Swiss authorities to help them to feed and clothe these children —Mr Harvey asked whether the Government had considered any suggestion by the International Red Cross for feeding these children —Mr Foot said that the Government had considered many schemes for what was called "controlled food relief" in enemy occupied territories, but they had come to the conclusion that all these schemes must bring benefit, and in some cases substantial benefit, to the enemy —Mr Rhys Davies asked if the House might take it as correct that the food supply to the occupied territories would be sufficient to prevent actual starvation in those territories —Mr Foot I should not like to give any undertaking as to the future

Appeal Tribunals

Sir W Womersley, replying to Sir Ian Fraser, said that H M Government remained satisfied that at present it is not possible to set up tribunals in sufficient numbers to deal with all the appeals which would inevitably be made On

CHALK IN BREAD

SIR,—In his letter under this heading in your issue of July 11 Sir E Graham-Little says ‘ Lord Horder was not appointed as adviser to the Minister until 1941 and could not be concerned with the decision [to add calcium] announced in July, 1940 ’ This is true but I should like to make it clear that when my view was asked, I concurred in the decision I was not so much influenced by what Sir Ernest calls the ‘ phytic acid bogey ” as by the fact that the calcium content of the war-time diet in general is prone to be low and by the absence of any convincing clinical evidence against the policy proposed

Ministry of Food, W. HORDER

THE THIRD DIMENSION IN DIAGNOSIS

SIR —I heartily welcome and endorse the views expressed by Major McGlashan He is not the only one who longs for the day when the physician will realise that neurology and psychology are concerned with human “ systems ” as different as the central nervous system is from (say) the digestive Mind is not brain and spinal cord, nor vice versa, and it is just as futile to send a case of “ nerves ” to a neurologist as it would be to send him to a gynæcologist, unless the neurologist himself be psychologically trained

One point, I think, needs to be added to what Major McGlashan says, which is that positive and permanent harm, which is far worse than mere waste of time and energy, may be done to a psychological case by applying physical methods to him whether for treatment or diagnosis There are two reasons for this One is that the glib use of bromides, luminal, etc , over long periods impairs the personality for good I have met with cases, which from all accounts should have proved good for psychotherapy, made quite incapable of rallying for the necessary effort owing to well-meant but misguided attempts to deal with his mental symptoms by soft-pedalling his nervous system with heavy drugs The other is because the hysteric inevitably wishes to find physical reasons for his troubles To focus on his body is merely to encourage and fix him in his bad ways until at last there is often no hope of persuading him to look for his cure in mental readjustment

We do need a three—and, indeed, a four- and if need be a five—dimensional approach to medicine, if we want to see the whole patient and deal with him on a basis of reality Else, when the present psychic strain is relaxed and our fears and phobias—at present conveniently projected on to Hitler and Mussolini—come home to roost in the minds of our patients we shall find many lives ruined by the application of methods good in themselves, but exerted on the wrong part of the man or woman concerned

Harley Street W 1 L J BENDIT

PSYCHOLOGY AND CHILDBIRTH

SIR,—Few of us who have been much concerned with the emotional changes that arise during the period of reproduction are willing to admit that Dr Ernest Jones's observations are of any assistance in the conduct of normal pregnancy and parturition Long ago I pointed out the importance of corticothalamic impulses acting on the neuromuscular mechanism of labour, and I described how the inhibiting influences of the sympathetic nervous system could be eliminated In most cases education and understanding have proved sufficient to enable a healthy woman to undergo pregnancy and parturition without any psychological complication Such teaching emphasises the beauty and the naturalness of childbirth, and the readiness with which women of all classes accept this point of view suggests that it is based upon instinctive belief rather than upon education alone

For the physician-obstetrician there can only be one line of thought He knows that childbirth is a natural function, he knows that culture has introduced numberless causes for justifiable fear, and he knows that most women are physically and mentally competent to produce their children according to the law of nature He is fully aware, having seen natural childbirth, that there is no experience in a woman's life comparable to the joy of seeing and hearing her newborn baby It is distasteful to us to be asked to bear in mind, when instructing our patients, the probability that the large majority of them have a pornographic visualisation of this supremely beautiful function A psychologist of standing said to me a few days ago that I must realise that the pains of labour represent the agony of castration in the female mind, for it is the final frustration of her desire to possess that which both in function and in form is male '

The fears that may complicate labour do not arise from fanciful ideas of childhood, either phallic or fæcal The normal woman provides no evidence either in her subconscious mind or in her behaviour that her infant is “ the bad thing,” the expulsion of which will either purify or injure her The healthy woman wants children and disbelieves her own fear of childbirth, but its horrors are so generally accepted that she cannot discard her anxiety She is nevertheless often ready to accept the truth from an authoritative source, and faith in her natural function defeats her fears To teach of the joys of childbirth and motherhood is to revitalise the true instinct, almost crushed by ages of social ignorance and academic oversight

If Dr Ernest Jones will allow that his address to midwives applies to psychopathic cases which, because of their mental condition, have abnormal labours, it is acceptable as a contribution to abnormal obstetrics

Woking G DICK READ

ILLNESS IN SMALLPOX CARRIERS

SIR —In your issue of July 11 Squadron-Leader Bowe raises the question whether an illness met with in close contacts of smallpox may be considered as that disease modified by vaccination In North India in the spring of 1939, four months after successful vaccination, I had for one day the care and nursing of a case of smallpox and was immediately revaccinated Twelve days later I had symptoms similar to those which I found, on my return to England, had already been noted by Conybeare (*Lancet*, 1939 i, 1125) In July, 1942, I was revaccinated with (as the public vaccinator put it) “ very satisfactory results ” At all events there were some scabs It seems therefore that after the illness in smallpox contacts described by Conybeare and Bowe there may remain liability to infection by smallpox

Oxford. D C WILSON

DOSAGE OF LOCAL ANÆSTHETICS

SIR,—Local anæsthetic drugs exert their undesirable central toxic effects after they have gained admission to the general circulation. The onset of these toxic effects depends on the concentration of the drug in the circulation at any given time This concentration does not depend only on the total dose of drug injected into the tissues, it depends on the balance between rate of absorption from the tissues into the blood-stream and the rate at which the drug is detoxicated in the liver or excreted by the kidneys The use of adrenaline to slow down the absorption of local anæsthetics into the blood-stream is universal, and the use of larger quantities of dilute solutions rather than smaller quantities of stronger solutions is becoming more popular for the same reason The other side of the problem has rather been neglected by anæsthetists ‘ Percaine ’ is chiefly detoxicated by the liver. It is probable therefore that the same types of patient who require small and carefully considered doses of ultrashort-acting barbiturates (which are also detoxicated in the liver) will require also small and carefully considered doses of percaine I suggest that in estimating the proper dose of a local anæsthetic for a given patient the general condition of the patient and the condition of the liver in particular are more important than the weight of the patient Dr Organe's first case (*Lancet*, July 11, p 33) was a man of 68 with intestinal obstruction This condition always leads to impairment of liver function The second case shows that tolerance of the local anæsthetic varied with the state of the liver The third case was complicated by respiratory embarrassment and the large weight of the tumours, but it is possible that the great pressure which was being exerted on the liver (sufficient to push up the apex beat 1½ in.) may have contributed to the convulsions by impairing the liver function

In Dr Organe's paper the maximum therapeutic dose of percaine in man is given as 2–3 mg per 16 kg I presume this is a misprint.

Colchester D CLENDON

⁂ The maximum dose recommended by Dr Organe should read 2–3 mg per kg body-weight.—ED L

Letters to the Editor

ANÆMIA IN HOSPITAL NURSES ON WAR-TIME DIETS

SIR,—The findings of Dr Mackay and her co-workers upon the hæmoglobin levels of hospital nurses, published in your issue of July 11, raise a serious problem in the welfare of these young women I have now completed a survey, carried out between November, 1941, and July, 1942, upon the hæmoglobin of 100 day and 25 night nurses at an EMS base hospital, staffed partly by the county authorities and partly by one of the large London voluntary hospitals The nurses from the latter training school move from one hospital to another within the sector, and also receive some of their training at their parent hospital, so that their dietary cannot be considered uniform My findings for the whole series are very similar to those of Mackay et al The average hæmoglobin, estimated by the Haldane method, for the day staff was 85 2% and for the night nurses was not essentially different, being 86 0% Of the entire series, 58% had hæmoglobin levels below the lower limit of normality (90% Haldane) given by Price-Jones (1931), while of these slightly over a quarter were below 80% The average age of the nurses examined was 23 years The menstrual history was obtained in every case and revealed that irregularity beyond the normal physiological variation was present in 29% , amenorrhœa and menorrhagia were present in about equal numbers Fourteen ward sisters (average age 29 years) were also examined and showed a higher average hæmoglobin level than that of the probationer nurses Their average was 91 4%

It appears that low-grade anæmia is common in the nursing profession at the present time These young women work 10 hours a day, often under trying circumstances, and this anæmia must contribute towards their feelings of fatigue and tend towards inefficiency I agree with Dr Mackay's conclusions as to the dietary nature of the anæmia and wish to support her suggestions both that non-fortified foods might be provided and that institutional diets should be under constant review during the present war-time conditions

Farnborough, Kent HELEN P WRIGHT

DIFFERENTIAL DIAGNOSIS OF DYSPEPSIA

SIR,—Commenting on the paper by Morton Gill, Berridge, and Arden Jones (in your issue of June 20), Sir Arthur Hurst and Dr Venables refer to our mucosal relief methods which, they state, had been used by Scott and by Briggs several years before Berg's work became known in this country In 1922 Scott wrote[1] of "whitewashing" the interior of the stomach wall, and went on

> "The gastric rugæ are in this way visualised and small ulcer craters can be detected among them, whether on the *anterior or posterior surface of the stomach I have found* that ulcers in these positions are frequently missed by most other methods, as the shadow of the stomach, filled with the meal, usually obscures them entirely The duodenal 'cap' and the duodenum itself are examined in the same systematic way The diagnostic value of radiograms in this examination has always been unreliable, except, of course, for the grosser lesions Consequently, I have been forced to discard them I maintain that any pathological condition that can be demonstrated on a radiogram can be visualised by this method of palpation, but that an ulcer visualised on the screen cannot always be demonstrated on a radiogram"

Scott makes no reference to any study of the mucosal relief pattern or to the physical characters of the mucosal folds in health and disease as shown by the X-ray Glimpses of the gastric rugæ were seen on the radiograms made in 1902 by Williams of Boston, who first succeeded in using an opaque meal in human beings It was not until Forssell made his fundamental studies of the mucous membrane and its autoplastic changes that Berg, amplifying these studies, began to portray the gastric and duodenal mucosa as part of his routine examination The fluoroscopic examination of the mucosa is part of this routine, but it is the recording of the appearances in black and white which is essential What is seen on the screen can now, and must now be recorded on the film—exactly the reverse of Scott's method We have not found any reference by Briggs to mucosal relief methods

Hurst and Venables are not convinced that the diagnosis of duodenitis is justified by our radiological observations But the existence of duodenitis as a clinical entity has been established by the clinical, macroscopic, and histological observations of Judd and Nagel,[2] MacCarty,[3] and Konjetzny[4] It is unfortunate, as Hurst and Venables point out, that the opportunity for histological control and confirmation of the radiological diagnosis of duodenitis is rare In our experience, this opportunity has only occurred on one occasion—in a case of true diverticulum of the duodenal cap with an associated duodenitis An illustration of this case has been published by one of us[5] Yet the absence of histological control does not, in our opinion, invalidate our radiographic interpretation of duodenitis Here we have patients with (1) a characteristic duodenal history, often extending over many years, (2) no radiographic evidence of an active chronic ulcer in the form of a niche, (3) no evidence of scarring changes in the duodenal cap to indicate healed ulceration, and (4) abnormal mucosal relief appearances which we have been unable to obtain in presumably healthy individuals These abnormal mucosal relief appearances are similar to those obtained in the stomach in gastroscopically controlled cases of gastritis We submit therefore that, as these abnormal mucosal appearances in the stomach are produced by gastritis, similar abnormal mucosal appearances in the duodenal cap will be produced by a corresponding lesion —e g , duodenitis

In referring to the observation by Morton Gill and his colleagues that "ulcers complicating duodenitis are usually superficial and appear to be implanted on the swollen rugæ" and that "they often heal rapidly leaving the duodenitis still present and apparently active" as purely imaginative, the choice of words is unfortunate We can endorse their observation It is not a unique experience to demonstrate on the film the niche of a superficial ulcer in a duodenal cap, the mucosal relief of which is characteristic of duodenitis If, after treatment, the abnormal mucosal relief can still be demonstrated and it is proved that the ulcer has healed by showing the ulcer scar on the film, it is surely a logical conclusion that the duodenitis is still present and apparently active, if the patient still has his symptoms

G R MATHER CORDINER,

Upper Wimpole Street, W 1 G T CALTHROP

HOSPITAL OR DOMICILIARY CONFINEMENT

SIR,—As a practitioner of 45 years' standing I was interested in Dr Menzies's article in your issue of July 11 I do not agree that fear plays an important part in the avoidance of pregnancy I have never been asked, "Will I get over it ?" but of course have often been asked by elderly primiparæ, 'Will I have a bad time because of my age ?'" I put this question to a district nurse of long experience, and she could only think of one case Antenatal supervision has not, in my opinion, frightened women

At first it was not understood, and the women needed educating, but now it is taken for granted and only in very rare cases refused Hospital deliveries are not, I think, necessary except where major operative treatment is required, or where poverty, filth and lack of accommodation make it impossible to treat a case properly With regard to breast-feeding, I am surprised that the hospital statistics show up so well, for my own experience is that a large percentage of women confined in hospital and nursing-homes come out with the baby on the bottle I agree with Dr Menzies that medical officers of health and other people in administrative posts get a wrong perspective of the dangers of midwifery because they are chiefly concerned with the deaths and with the notifications of septicæmia Generally speaking, the average case attended at home is so straightforward that it can be safely attended by the midwife only—as the facts themselves show

Brewood, Stafford G P JAMES

made up to the new permitted formula). On the other hand Hess in his volume "Ueber den Suss-stoff Dulcin" (Berlin 1921) carefully reviews the facts and concludes that dulcin in quantities likely to be consumed is harmless, and Taschenberg (*Dtsch med Wschr* 1922, 48, 695) arrives at the conclusion that dulcin in amounts greater than necessary to replace sugar has only an insignificant, if any, toxic action. Admittedly the last-named was mainly concerned with the antipyretic action but his researches were carefully conducted and other toxic symptoms were not observed. Attention may also be drawn to Siedler (*Chem Ztg* 1916 40 853), who after reviewing pharmacological and clinical data on the use of dulcin concludes that in quantities likely to be consumed it is harmless to man and experimental animals. Further the new tablet permitted by the Ministry of Food order contains 0.06 grain of dulcin and 250 such tablets must be consumed to obtain one gramme of dulcin; it is extremely improbable that any person will consume more than one tenth of this quantity daily. I have observed a number of individuals who have consumed this amount—i.e., 25 tablets daily—over a period of some months, in order to see whether a cumulative effect exists, but no ill effect has been observed. It is of course possible that an idiosyncrasy towards dulcin may be met with; but I have been unable to obtain any account of such a case.

I have had experiments carried out on the decomposition of dulcin by autoclaving a solution buffered in citric acid/sodium citrate to pH = 4.0. After two hours at 240° F, 70 per cent of the dulcin remained; of the remainder the bulk is converted to insoluble inert products and of *p*-aminophenol only a trace is obtained. Thus, in cooking or canning, the hazard of toxic breakdown products is negligible and need not deter its use.

Care should be taken by users to see that any dulcin purchased is pure; reputable manufacturers ensure this by working to a standard, but parcels of poor quality dulcin in circulation may contain impurities which are more of a danger than is dulcin itself. It is probably the presence of such rapidly inert materials that led your correspondent to observe that dulcin is a good deal less sweet than is claimed. The accepted figure is that dulcin will replace 250 times its weight of sugar and this has been checked by a large variety of observers, both by the method of limiting dilution and by practical baking tests. A sound commercial dulcin should be of a white or pale pink colour, m.p. not lower than 168° C, ash negligible, entirely free from phenetidine or its salts and should assay at 99%+ as *p*-phenetyl carbamide, after deducting moisture which should not exceed one per cent.

G. M. DYSON,
Chief Chemist.

Genatosan Ltd.

DIPHTHERIA IMMUNISATION

SIR,—The desirable object of encouraging diphtheria immunisation is ill encouraged by the present film propaganda, which reveals a simple hypodermic injection being given to an infant in the wrong manner and the wrong place. The infant is overwhelmingly overpowered and the actual injection is given most aggressively. The seat of election for any hypodermic injection should be chosen on the less sensitive extensor or dorsal aspect of the limb or body. Perhaps it has not yet been taught where injections should actually be given. The neighbourhood of the antecubital fossa is predominantly useful for intravenous administrations, but the film suggests that this fossa is being used like a dartboard, with needless pain to the child and causing repulsion in the parent.

Walton-on-the-Hill. G. C. SNEYD.

MEDICAL HONOURS.—The MBE has been awarded to Captain (temp. Major) G. F. Edwards, MB LOND, RAMC, for gallant and distinguished services at Malta.

MEDICAL CASUALTIES.—The following have been announced:

Missing presumed killed in the loss of HMS Dorsetshire.—Surgeon Commander F. C. M. Bamford, MB GLASG, RN, T/Surgeon Lieutenant S. W. Pratt, MB LOND, RNVR.

Missing.—Lieut.-Colonel Gerald Condon, LRCPI, IMS, at Tobruk; Major A. C. Glendinning, MB BELF, IMS, in Malaya; Colonel G. P. Kidd, MC, MRCS, RAMC, in the Middle East; and Captain N. C. Rogers, MB LOND, RAMC, in Libya.

Wounded.—T/Surgeon Lieutenant G. P. Fahrni, RCNVR.

STAMPS OR TAXES?

Two trends can now be seen in our social services, results of economic changes brought about by the war. One is the suggested inclusion of dependants in National Health Insurance with the development of consultant, diagnostic and possibly inpatient facilities not at present provided. Such an extension of the panel would cover 90% of the population; so that the method of weekly contributions, cards and stamps would become in effect a somewhat cumbrous way of excluding 10% of the population from an otherwise general scheme. The other trend is the provision by the state, out of taxation, of social services to those with special needs, irrespective of their individual contribution. Examples of such services are medical attention for evacuated children and air-raid casualties, and war pensions. Until recently industrial workers contributed to the funds for social services by indirect taxation and contributory insurance, income-tax being paid by a relatively smaller group. The number of tax-payers has now greatly increased, partly owing to the lower level at which income-tax is levied and partly to the increase in absolute (not relative) wages. If these opposing trends develop unchecked we may find that our social services, while requiring more machinery, are becoming less efficient. We have 1001 voluntary agencies providing services to small groups in the community, and nearly 7000 approved societies handling (piecemeal and with considerable running costs) social insurance which in the view of PEP[1] is neither genuinely social nor genuinely insurance. Indeed, as an experiment in democracy, PEP feels that approved society administration of NHI cash benefits is almost a complete failure, and suggests that the only approved society needed is the nation itself. It is true that less than 34% of the expenditure on state pensions from 1926 to 1938 was covered by contributions and interest; all the rest had to be found by the state, out of taxation.

The cost of administering the various insurance benefits varies enormously. It cost only £750,000 to distribute the Ministry of Pensions cash and medical benefit of £42 million; but it cost £6 million to administer £35 million worth of NHI cash and medical benefit, and £4 million to administer £9 million of Workmen's Compensation payments, and the companies and collecting societies doing industrial insurance collected £65 million in premiums and distributed £33 million in benefits at a cost of £22 million. There are thus substantial possibilities of cutting out waste and extravagance, though the method will need consideration. The London County Council on July 28 expressed to the Beveridge Committee its preference for one comprehensive scheme of social security (blindness excluded) administered centrally to provide adequate cash benefits for all needs and risks "actuarily ascertainable," personal services remaining the concern of local authorities. PEP advocates the creation of a Ministry of Social Security to examine and deal with the distress resulting from unemployment, injury, disease, widowhood and old age, as parts of a single problem. There should be a common standard of minimum human needs in terms of which allowance rates and scales can be framed, and a human needs family budget might be the basis of a revised minimum cost of living index. Coupled with this there would have to be minimum wage legislation and family endowment.

On such a basis adequate income-maintenance allowances could presumably be provided. The new ministry would necessarily absorb the personnel and functions of existing public and private agencies. Its funds might be raised by state grants, local authority rates, workers and employers contributions, and from charges on employers; but chiefly by direct taxation of all incomes. PEP sees the local administrative unit of the ministry as a single social security office for all departments, but proposes that unemployment benefit should be administered from a special office at the employment exchange, and sick benefit at health centres. Many payments could conveniently be made as now through post offices. Defects and abuses of the present system of workmen's compensation have been well catalogued by the late Sir Arnold Wilson and Prof. Hermann

DECLINE IN MENTAL HOSPITAL ADMISSIONS

SIR,—On p 51 of your issue of July 11, the Minister of Health is reported as describing the decline in mental hospital admissions since the war as "an eloquent testimony to the nerves of the nation," while on p 50 Medicus, M P, wonders "if this is due to a passing phase or to deeper mental and physical causes" The matter was briefly discussed at a meeting of psychiatrists which I attended some months ago, and here a general opinion was expressed that the principal cause was the fall in unemployment The low incidence of mental disorder in the USSR is possibly also due largely to the low rate of unemployment in that country The fact that discharged patients now find little difficulty in obtaining work, in contrast to prewar conditions, seems to be a contributory factor in the lessening of relapses Before the war one noted in a considerable number of cases that the onset of a psychosis had been preceded by a long period of unemployment before the ultimate breakdown took place, it is not difficult to appreciate the mental and physical stresses involved

If these impressions are correct—and I would stress that they are only impressions, and not scientifically checked observations—then in the postwar period the remedy for these ills will be in the hands of the politicians rather than in those of the doctors It is to be hoped, however, that the doctors will then give the politicians a firmer lead than the nebulous wonderings of Medicus, M P, and so render it unnecessary for a future Minister of Health to indulge in pious non-sequiturs like that quoted above

St Bernard's Hospital, Southall, Msx J B S LEWIS

SOLDIER'S DOCTOR

SIR,—As a commander of a field ambulance in the last war I got to know a good deal about MOs They do get pushed around at times There were two types liable to this First, the men who are good at this work They adapt themselves and pick up the new conditions rapidly, but never really get into the home life of the unit (They are needed in civil life as well as military and do holiday work at places sometimes year after year) The other type is those who, like your correspondent of July 18, are always telling us they are square pegs put into round holes They are not, they are discarded bricks incapable of malleability and shaped so as to fit into one hole only We had such MOs in the last war One insisted on doing his sick parade in the morning in pyjamas and gum boots He was moved on Another signed up half an RE company as being inoculated against typhoid without having done any of them This was discovered a year later but the divisional commander would not have him court-martialled because he had a high opinion of the medical profession and did not want a scandal to besmirch it This was wrong He would probably have been cashiered, and then struck off the register, and thus have saved the insurance committee of the area in which he worked afterwards a lot of trouble, and the profession as bad a reputation in that area as that which it had with the units of the RE and RA to which he was attached

After the CO the MO has the greatest influence in the unit for good or bad of any officer in it We had good MOs as well I need not describe them, because there are good ones in this war also There is for instance Z who went back to the battalion he was with in the last war and has refused to leave, in spite of bribes of a majority and a specialist job There is little Y who with a stammer on his tongue and a blinking of his lids, but always a twinkle in the eyes beneath, had to be lugged out of the back of the class Two years ago turned up with a ribbon on his breast We learnt that he had walked across Belgium with a cracked head, but could not for the life of us find out why he got that MC Questions only brought back the stammer and the blink and the statement that those fools of doctors insisted on his going into hospital but they had let him out again now and he was going back to the battalion A month ago he popped in again, on leave before going overseas once more with the same battalion But he was a different man Two inches taller, with his head erect, his shoulders thrown back, the stammer and the blink gone, but still with the twinkle in the blue eyes, he had a way of putting his foot down that made the old fogey wonder whether there might after all, be as good battalions in this war as there were twenty-five years

Of course it may be that this war so differs from that one that doctoring as well as troop movement and gunnery is ineffable to the old-stager It is unlikely Human nature is unchanged The seriousness of the tone of your correspondent's letter lies in the fact that it may tip a fellow over into joining the Services with his mentality rather than that of ageing Z and young Y And, though there are a regrettable number about of the British matron's babies mentioned in the opening sentence of your leading article, there are many going in with heads erect, but they are the little men at the back of the class and not those that throw their weight about the hospitals and get the best house-jobs

FOGEY

"DANGERS OF DULCIN"

SIR,—Dr Shackle draws attention to the fact that one article by Uglow and one by Rost and Braun have not been contradicted My answer is that his inferences from those articles are misleading Uglow quotes a statement by a pharmacist that boiling (cooking is not a correct translation in this instance of the German "kochen") of faintly acid, neutral or basic solutions of dulcin led to the formation of *p*-amidophenol He himself claims that such hydrolysation takes place only when boiling for 2½ hours with caustic soda or mineral acids As a matter of fact it is known that an alkoxy group is one of the most stable aromatic radicals, and can be hydrolysed only by heating with strong mineral acids under considerable pressure Uglow refers to one ingenious method—covered by a German patent—for preparing dulcin by heating diphenetidin carbonate with ammonium carbonate or urea (i e, in strong solution) under pressure at 160° C I may mention that vanillin, used as a food flavouring agent, which contains a methoxy group is prepared by oxidising isoeugenol in 12–15% caustic soda solution at about 120° C

One must bear in mind the exceptional circumstances under which the experiments, referred to by Uglow, were carried out I happened to be in Russia in 1923, and am well aware of the, extreme lack of technical and research facilities in that country at that time, let alone in 1917–18 The best method used in those times for preparing *p*-phenetidin, from which dulcin was made, was by combining *p*-amidophenol with benzaldehyde, and the benzyliden-*p*-aminophenol thus formed was ethylated with ethyl bromide The benzylidene *p* aminophenetol was then hydrolysed with mineral acid, whereby benzaldehyde was recovered and *p*-phenetidin obtained It is possible that during such hydrolysation some *p*-aminophenols were formed and that the dulcin then prepared in Russia was contaminated with them The most relevant report is that by Professor Lichatschoff to the effect that dulcin is partly converted into *p*-amidophenol by certain animals, such as dogs, but he adds that it is quite harmless when used in small doses by healthy human beings The report by Rost and Braun confirms this The fatal case quoted by them of a child consuming 8–10 g is hardly surprising, such a result would probably follow when a child partook of a similar quantity of any other condiment used in cooking

Dr Shackle does not mention another report by Uglow (*Arch Hyg Berl* 1923, 92, 331) on saccharin, which is far more damnatory than his attack on dulcin

Hendon L G RATNER

SIR,—Your correspondent's fears on the toxicity of dulcin evidently spring from a right and proper regard for care in the use of substitutes, as far as dulcin (*p*-phenetyl carbamide) is concerned, he can rest assured that the likelihood of toxic symptoms arising from its use is very remote As one who has for many years been concerned in research on this material, I should like to comment as follows on Dr Shackle's letter

He quotes Rost and Braun's article of 1918, but their subsequent work (*Arb ReichsgesundhAmt* 1926, 57, 212) should be read in its entirety, it states that, like all phenetidines, dulcin in massive doses has a marked toxic effect on the central nervous system, and a slight one on hemoglobin, especially in young animals Their idea of a massive dose is 5–10 grammes (equivalent to 3–5 lb of sugar in sweetness, or to 1250–2500 tablets

Public Health

Smallpox in Swindon

FOUR of the passengers on the infected ship that berthed at Glasgow on May 28 reached Swindon on June 1 and were there kept under observation On June 7 a baby was reported ailing and slightly febrile He was well again on the 8th and 9th ; on the 10th a slight erythema appeared on the inner sides of the thighs with one definite pock on the lower abdomen The child was confined to the house but did not look like smallpox until the 12th, when papules were felt on the forehead and on the extremities, and he was removed to hospital All known contacts were vaccinated and kept under observation One contact a child was unwell on the 22nd and on the 25th had a rash like a sweat rash on its thighs By the 26th this child also had distinctive signs of mild smallpox Vaccination was noted as a good take on the 22nd A third child, a sister of the second was removed to hospital on July 1 because of an erythema of the thigh, but nothing further developed On June 26, the day after the second child was removed a man came under observation who had been ailing since the 22nd, when he had headache and stayed away from work but was well enough to visit his doctor on the 24th On the 26th he had a definite papular eruption most marked on the face neck and forearms, where he had been exposed to the sun on the 21st He was removed to hospital where he developed a moderately severe semi-confluent type of smallpox

Dr Llywelyn Roberts informs us that these are the only cases of smallpox seen to date (July 20) in the town, but much confusion has been caused by skin eruptions following vaccination which in some cases simulated a commencing attack of smallpox

War and the Public Health

Dr Neil Reid county medical officer of Stirling, published his annual reports for 1938, 1939 and 1940 in one volume which makes it easy to follow the history of public health from its record year 1938 through the early phases of the war era Though the county has but 175 000 inhabitants and is not a just sample of the population of Great Britain, the changes in the health of the people there are similar to those recorded elsewhere Generally health declined from 1938 but we are not justified in attributing this to war conditions for 1938 was the culmination of a series of years of exceptionally healthy conditions and some decline might have been expected in any circumstances The two severe winters of 1939 and 1940 would of themselves have reduced the record of the previous years, so we must try to estimate whether the deterioration is greater than would have occurred in peace The birth-rate, which was 18 5 in 1938 and 18 6 in 1939 fell to 17 3 in 1940 The two first rates are slightly above the average for recent years ; the rate for 1940 was a low record for the county. Infantile mortality showed a brisk rise—53, 62, 74—but the rates for 1936–38 were 74, 69 53 The average rate for the past decennium was 70, but this was exceeded in seven years out of ten. The general death-rates for the three years were 10 8, 11 7, 13 0 but as the average for the five preceding years was 12 0 it is the low rate of 1938 which was exceptional The tuberculosis mortality-rates were 0 44 0 39 0 45, the three lowest rates ever recorded in the county The tables of notifiable diseases show three very quiet years with recorded total numbers of 1086, 864 and 747, the only unfavourable features being increases in cerebrospinal fever and pneumonia The numbers of cases of notifiable pneumonia were 107, 107, 142 The brisk rise in 1940 is no more than would be expected from the severe winter of that year. On the whole there is no evidence that war conditions had any influence at all on the health of the community and this is true for most of Britain From tradition we expect war to be associated with pestilence, but the history of Britain in the past hundred years shows no such connexion None of the great epidemics of the century occurred in the great wars, except that the influenza epidemic of 1918 started before the last great war was over and the two most recent epidemics of cerebrospinal fever appeared in the last war and in this The great London epidemic of cholera—the famous Aldgate Pump outbreak of 1854—did occur when the Crimean War was in progress, but it was only an exacerbation of an epidemic which had been raging for ten years or so The influence of war in increasing tuberculosis mortality seems to be established, but the break in the downward course of tuberculosis characteristic of the last war period started before war was declared and the same is true of the slight rise associated with the present war

Infectious Disease in England and Wales

WEEK ENDED JULY 18

Notifications —The following cases of infectious disease were notified during the week smallpox, 1 (port of Liverpool) , scarlet fever, 1558 , whooping-cough, 1295 diphtheria, 692 , paratyphoid 6 ; typhoid, 5 , measles (excluding rubella), 7050 pneumonia (primary or influenzal) 516 , puerperal pyrexia, 155 ; cerebrospinal fever 83 , poliomyelitis 16 , polio-encephalitis 1; encephalitis lethargica, 2 , dysentery 198 , ophthalmia neonatorum, 106 No case of cholera plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on July 15 was 1549, including scarlet fever, 225 diphtheria 157 ; measles, 401 , whooping-cough 278 , enteritis 57 , chicken pox 83 , erysipelas, 29 , mumps 57 , poliomyelitis 2 , dysentery, 39 , cerebrospinal fever, 13 puerperal sepsis 13 german measles, 8 , other diseases (non infectious), 115 , not yet diagnosed, 72

Deaths —In 126 great towns there were no deaths from scarlet fever, 1 (0) from an enteric fever, 7 (1) from measles, 13 (3) from whooping-cough 8 (0) from diphtheria, 37 (3) from diarrhœa and enteritis under two years, and 10 (1) from influenza The figures in parentheses are those for London itself

Hull reported the fatal case of enteric fever There were 6 deaths from diarrhœa at Birmingham and 4 at Liverpool

The number of stillbirths notified during the week was 233 (corresponding to a rate of 38 per thousand total births), including 20 in London.

Appointments

DOWELL, T L , MB LPOOL examining factory surgeon for Bentham, Yorks

FRANKS HAROLD, MB BHY DURH DPH temp deputy MOH and deputy School MO for Barking

HESELTINE, L B MB LEEDS examining factory surgeon for Brighouse Yorks

GILBERT FRANCIS SYMS

F R C S SURGEON REAR-ADMIRAL RN

Admiral G F Syms died on June 23 at the age of 59, after a period of ill health during which he insisted on remaining at his post He qualified from Guy's in 1908 and entered the Royal Navy the following year In 1914 he was awarded the Gilbert Blane medal and at the end of that war he was promoted surgeon commander After taking his FRCS in 1923 he was posted to Plymouth Naval Hospital as surgical specialist In 1934 he became professor of surgery at Haslar and five years later he returned to Plymouth to take charge of the hospital The King of Denmark appointed him a knight of the order of Dannebrog in 1922 and last year he was made an honorary surgeon to King George VI

An old colleague writes "Gil" and his wife "Joe" were dear friends of my family It was my misfortune to have to break the news to him some years back that his operation caused us all alarm Never have I met a braver man for his knowledge of surgery must have told him that he was doomed He faced it squarely—only to be met by further affliction His eldest son was killed and his daughter widowed by the war I stayed with him in his last appointment Despite declining health and bombing he bore the brunt though he could have reported sick and spent his remaining years in the peace and quiet of the country

THOMAS CLOVER LARKWORTHY

M B CAMB, SURGEON COMMANDER RNVR

Surgeon Commander T C Larkworthy, who for many months had been reported missing following the loss of HMS *Neptune*, is now officially presumed killed A great-nephew of Joseph Clover, who gave his name to the inhaler, he was educated at Bradfield and Emmanuel College, Cambridge, and qualified at St George's Hospital in 1928 After holding house-appointments there and at the Brompton, he obtained clinical assistantships at the Victoria Hospital for Children and in the infant department at St George's He joined the RNVR soon after qualification, and continued in the service after entering general practice in Kensington At the outbreak of war he held the rank of lieutenant commander, and after serving ashore for a time was posted to HMS *Curacoa* His experiences off the Norwegian coast, for which he was mentioned in dispatches, were described in the *Journal of the Royal Naval Medical Service* His promotion to surgeon commander soon followed

Larkworthy possessed qualities of sound judgment and knowledge, kindness and unselfishness and these qualities had already assured his success in practice, for his patients soon recognised that he did his work well without fuss or striving to impress He was a keen freemason, and in this, as in everything he did, showed his capacity for understanding and making friends He was thirty eight years of age, and he leaves his widow with three small daughters

ANTHONY RICHARD BARRETT

M B N U I, TEMP SURGEON LIEUTENANT RNVR

Surgeon Lieutenant A R Barrett, who was reported "missing presumed killed in action" last December, was the younger son of John Barrett of Bangor Erris, co Mayo The family came from Wales and settled in the barony of Tyrawley in the West of Ireland in the twelfth century, holding their property there by grant from King Henry II Anthony, who was born in 1915, was the namesake of his ancestor the Celtic poet of the early nineteenth century He was educated at St Muirdeach's College, Ballina, where he matriculated to the National University of Ireland at the age of sixteen As a resident student of the Richmond Hospital, Dublin, he graduated MB with honours from University College, Galway, in 1937 After a trip to the Far East as ship surgeon he was appointed senior house-surgeon at the Caernavon and Anglesey Infirmary at Bangor, and in 1939 he joined the staff of West Ham mental hospital as assistant medical officer His genial temperament and shrewd wit made Billy, as he was affectionately called, a pleasant companion He was a sound physician and his growing enthusiasm for psychiatry won the respect of his colleagues He married Madge MacDonagh of Ballymote, co Sligo

WILLIAM MARTIN

M B GLASG

Dr William Martin, who died suddenly on July 7, had been medical superintendent of Stobhill Hospital, Glasgow, since 1927 He was a graduate in medicine of Glasgow University, qualifying in 1914 He joined the Army in 1915 during the last war, and served in France with the rank of major On his return to this country in 1917 he was appointed to Dudley Road Military Hospital Birmingham, and three years later he became medical superintendent of Selly Oak Hospital

Dr Martin's influence as an administrator extended beyond his own large hospital at Stobhill In 1929, after the passing of the Scottish Local Government Act, Glasgow corporation appointed him deputy medical officer (general hospitals) in their public-health department He brought about great improvements at Stobhill A large X-ray and electrical department was built, the maternity unit was enlarged, a receiving department and a biochemical laboratory added, and plans had been prepared for a block for sick children and a nurses' home He also took a prominent share in developing teaching facilities in the hospital, and he was an able and friendly collaborator in developing the cooperation of the university and city in medical teaching and research

Dr Martin was content with nothing but the best, but he was never ruffled by difficulties, and his happy and cheerful disposition attracted the friendship of all who served in his hospital

CONSERVATIVE HEALTH AND HOUSING COMMITTEE —At a meeting of this committee held on July 21, under the chairmanship of Sir Francis Fremantle, Lieut-General Alexander Hood, DG AMS, gave an encouraging account of health conditions in the armies at home and abroad, though increased vigilance will be necessary during the winter when hutments and billets have to accommodate increasing numbers With various advisory bodies to keep them in touch with civilian practice, his department was now organised on a basis that ensured complete medical service for the troops Mr Hugh Linstead was elected deputy secretary of the committee to assist Captain G S Elliston, who has been hon secretary since 1931

PNEUMONIA TREATED WITH SULPHAPYRIDINE AND SULPHATHIAZOLE

CONCENTRATION OF THE DRUGS IN THE BLOOD

FREDA K. HERBERT, M.A. CAMB., M.B. LOND
LECTURER IN CHEMICAL PATHOLOGY AT THE MEDICAL SCHOOL, KING'S COLLEGE, NEWCASTLE-ON-TYNE

E. F. DAWSON-WALKER
M.D. DURH., D.P.H.
MEDICAL SUPERINTENDENT OF THE CITY HOSPITAL FOR INFECTIOUS DISEASES NEWCASTLE-ON-TYNE

W. G. A. SWAN
M.D. DURH. M.R.C.P.
ASSISTANT PHYSICIAN TO THE CARDIOVASCULAR DEPARTMENT AND MEDICAL REGISTRAR AT THE GENERAL HOSPITAL

THE present work was begun in the spring of 1940, when little was known of the pharmacology of sulphathiazole. We thought it would be useful to compare sulphathiazole with sulphapyridine in the treatment of lobar pneumonia; it seemed at the time that sulphathiazole might be less toxic than sulphapyridine and little if at all inferior in bactericidal action against the pneumococcus. Since the bactericidal effect depends on the concentration of the drug in the blood and tissue fluids, it was necessary to base the comparison between the two drugs on blood analyses rather than on dosage alone. The plan of work was therefore to carry out clinical trials with both sulphathiazole and sulphapyridine, with analyses of the blood at short intervals during the whole course of treatment.

Pneumonia was not very prevalent during 1940 and the number of cases studied is small—too small for an assessment of the relative therapeutic value of the two drugs. Since our work began, however, several American workers have published the results of clinical trials on very large numbers of cases, which show that sulphathiazole has no special advantage over sulphapyridine, except that it is less likely to cause nausea and vomiting. We therefore present our findings, primarily to show the concentrations of the drugs in the blood on a given dosage.

MATERIAL AND METHODS

Only the free drugs in the blood were estimated. The technique was essentially that of Marshall and Litchfield (1938) with some differences in detail.

Whole blood, 1 c.cm., is measured into 15 c.cm. of distilled water. After thorough laking of the corpuscles, 4 c.cm. of 15% trichloracetic acid is added, the mixture is shaken, allowed to stand for ten minutes and filtered. To 10 c.cm. of filtrate 1 c.cm. of sodium nitrite solution (0·1% freshly made) is added; the mixture is shaken and allowed to stand for three minutes; then 0·1 c.cm. of urea (5%) is added, the mixture is shaken and allowed to stand for two minutes; finally 1·9 c.cm. of phosphate buffer (M/1 KH_2PO_4) and 5 c.cm. of dimethyl-α-naphthylamine (0·4% by volume in 95% alcohol) are added; five to ten minutes are allowed for full development of the red colour, which is either measured in the photometer or compared in the colorimeter with a standard solution of the drug treated in the same way as the blood filtrate. Most of the measurements in this work were made in the Pulfrich photometer, using the filter S 53, and working with a control mixture in the compensating cell, prepared from the reagents alone with water in place of blood filtrate.

It was found that the method described by Marshall (1937) for the estimation of sulphanilamide gave low results when applied to sulphapyridine or sulphathiazole. In experiments on recovery of known amounts of the drugs added to blood, the values found ranged from 60% to 80% of the true figure. Marshall and Litchfield (1938) recommended destruction of excess nitrite with ammonium sulphamate. We used urea for destruction of nitrite; it improved the recovery of the drugs added to blood, but the results were still low. Buffering of the final mixture to pH 1·8 hastened the rate of colour development without altering the final reading. Finally, it was found that the recovery of the drugs added to blood was more satisfactory if the dilution of blood at the stage of protein precipitation was 1:20 instead of 1:10 as in the original method. Even in the method finally adopted the recovery of the drugs added to blood was only 90% of the true figure, but the loss was almost constant and the appropriate correction could therefore be made.

The series consisted of 30 cases of lobar pneumonia occurring between April, 1940 and January, 1941. There was no epidemic of pneumonia during the period, and the type of infecting pneumococcus varied so widely that nothing would be gained by describing the incidence of the different types. The ages of the patients ranged from 16 to 79. Alternate cases were treated with sulphathiazole and with sulphapyridine, without selection; 16 cases received sulphathiazole and 14 sulphapyridine. In the sulphathiazole group 11 patients were under the age of 30 and the eldest was 79: in the sulphapyridine group 10 were under 30 and the eldest was 58. In every case the free drug was given by mouth. Doses were given four-hourly. The standard dosage for sulphapyridine was 2 g. for the first three doses, then 1 g., continued until the temperature had definitely settled and the clinical condition was improving. The earlier cases treated with sulphathiazole received the same dosage as the group receiving sulphapyridine; later the dosage of sulphathiazole was doubled. The full dosage according to these three regimes was continued for periods ranging from 60 to 96 hours according to the clinical indications: in some cases treatment was continued at reduced dosage for a further period. Samples of blood for analysis were taken thrice daily at four-hourly intervals, the blood collections being made at the mid-point between doses of the drug.

CLINICAL RESULTS

Both drugs were effective in producing defervescence and clinical improvement. Apart from 3 cases with special complications the time taken for the temperature to fall to normal was eight to fifty-six hours, and was usually within twenty-four hours. There was no significant difference in the rate of defervescence between the groups treated with the two drugs, and no apparent relation between the rate of defervescence and the concentration of the drug in the blood.

Of the patients treated with sulphathiazole, 1 died, a man of 79 who was gravely ill when treatment started. There was temporary improvement after one day of treatment, but he relapsed and died on the third day. There was one death also among the patients treated with sulphapyridine, that of a man of 51.

Leucocyte counts were made daily in all cases and varied widely. In the group treated with sulphapyridine 12 showed a fall in leucocytes during treatment (maximum fall 23 400 cells per c.mm.), 3 showed no change and in 1 case there was a rise. In the group treated with sulphathiazole 9 cases showed a fall (maximum fall 23 000 cells per c.mm.), 3 showed no change and 4 showed small rises. There was no relation between the changes in the leucocyte count and the clinical course of the disease.

TABLE I—URINARY ABNORMALITIES IN PATIENTS TREATED WITH SULPHAPYRIDINE AND SULPHATHIAZOLE

—	Sulphapyridine	Sulphathiazole
Total cases	14	16
No. with urinary abnormalities	9	12
Albuminuria	8*	10
Gross hæmaturia	1	0
Microscopic findings		
Red cells	5	3
Pus cells	3	6
Casts	3	2
Suppression of urine	0	1

* One patient had acute nephritis on admission.

The only toxic effects seen were vomiting and renal abnormalities. Vomiting was troublesome with both drugs, but was slightly commoner with sulphapyridine than with sulphathiazole: 10 out of 14 patients receiving sulphapyridine vomited, and 6 out of 16 receiving sulphathiazole. It should be noted, however, that 10 of the patients treated with sulphathiazole received double the dose used for the group on sulphapyridine, and 4 of the patients who vomited were on the higher dosage. It is difficult to say how far the renal abnormalities were due to treatment, since toxic damage to the kidney may occur in the untreated disease. The incidence of urinary changes is shown in table I.

Notes and News

IN TIME OF NEED

THE Professional Classes Aid Council (20, Campden Hill Square, London, W 8) was formed to help people through difficult times Most of the benevolent funds of the professional associations, including the RMBF, are represented on it and wasteful overlapping is avoided while helpful cooperation is fostered War has increased its work but decreased its income, and last year's deficit of £889 has grown to £1184, though £1124 less than last year was distributed The decrease of nearly £1000 in subscriptions and donations is partly due to the reduction in income-tax allowed to charities under the Finance Act of 1941 But in spite of these hindrances 319 families were helped with money during 1941–42, and many others were advised of appropriate sources of assistance Special annual grants were given to 31 people, and 134 children—67 boys and 67 girls—were helped with their education It is in this part of the council's work that the distress and hardship caused by the war is most clearly to be seen, for many women whose husbands are missing in the Far East have suddenly found themselves without money for the maintenance of schooling of their children Fewer students have applied for training grants this year but most of them have had to ask for larger sums Fifty—17 men and 33 women—were accepted and some of them have chosen medicine, physical culture, social work and nursing as their careers Over £3000 has been spent on what is called general help, of which just over £2000 went in temporary maintenance grants to applicants, many of whom were helped to obtain permanent grants from other sources Sums were also allocated under this heading for outfits, payment of life assurance premiums, and arrears of rent The council was one of the good things that emerged from the last war It is up to us to see that at the end of this one it is fighting fit

A GOOD START FOR CHILDREN

THE National Council of Women has made representations to the Minister of Health and the Chancellor of the Exchequer on the subject of financial allowances for women during pregnancy and lactation War, the council find, has aggravated a position which was already unsatisfactory More married women are entering industry or non-industrial occupations, and though some firms send expectant mothers off duty for some weeks before and after labour others do not, and in any case the mother cannot be prevented from taking up alternative work during the interval—except factory work which the law forbids for 4 weeks after a confinement Under existing arrangements the financial alternatives to ordinary wages are not adequate to make a woman willingly give up work, yet the health of the coming generation is going to be affected by the wellbeing of the mother during the last weeks of pregnancy and the time of lactation The financial difficulty falls on both insured women and the uninsured wives of insured and uninsured men Long-term planning to meet these difficulties, as the council recognise, is the province of the Interdepartmental Committee on Social Insurance and Allied Services, but there is need too, they feel, for an interim scheme to tide us over if we are to avoid producing a sickly generation The council holds that a woman should be debarred from working in any paid employment during the last 8 weeks of pregnancy and the first 8 weeks of lactation if she is to come to term fit for labour and if the milk flow is to be properly established They realise that extension of national health insurance legislation is hardly practicable just now, but they suggest that the approved societies might interpret more widely their duties in paying sickness benefit to insured pregnant women At present pregnancy is not recognised as incapacitating, and though many approved societies allow payment of benefit during the last three or four weeks of pregnancy some discourage even this concession so strongly that the women do not even make a claim Failure—whether real or anticipated—to obtain sickness benefit discourages women from giving up work as soon as they should in the interests of the child If a mother does give up work and then finds she is not eligible for sickness or unemployment benefit she is likely to be very short of money, moreover, her future title benefits under the NHI Act may be prejudiced for a thing up to two and a half years

Approved societies have agreed—on the request of Minister of Health—to relax their rules in regard accepting married women war workers as memb The council asks that the societies should go further announcing that as a war-time measure they are will to recognise the last 8 weeks of pregnancy as a period incapacity within the meaning of the act A certific from the doctor or midwife might be accepted as ev ence This would better the position for insured wome but women who are not insured are equally in need help, and so are those who have only qualified for minimum rate of sickness benefit or whose husbands not entitled to draw maternity benefit In any c full sickness and maternity benefits are not sufficient cover the extra expenses which spring up at the birth c baby The council would like an allowance to be m to all women during the last 8 weeks of pregnancy a the first 8 weeks of lactation—an allowance large enou with NHI benefit, to compensate the employed wom during her incapacity and to give the unemployed wom enough to meet additional expenses Such an allowan the council feels, would be an appropriate emerge supplement to children's allowances which may introduced as a temporary measure while the Int departmental Committee are deliberating on a m permanent policy

MAKING USE OF THE DISTRICT NURSE

THE full value of the district nursing service is not appreciated by doctors with panel practices, as chairm of the Greater London Provident Scheme for distr nursing, Lord Horder writes to remind us of this quotes the case of a worker at an aircraft factory w was off work for a fortnight with cellulitis During th time her doctor advised her to rest, but also to atte at his surgery—which meant a considerable daily wal Had he put her in touch with the district nurse she could have been spared these journeys, to the advantage of her condition The Ministries of Health and Labour have both insisted on the importance of close cooperation between the factory medical officer, nurse or welfare officer and the local district nurse and the panel doctor, and there is every reason for the panel doctor to make good use of the district nurse's help at a time when he himself is liable to be overworked A sympathetic liaison between them begun now will help to establish the new era in social medicine to which we all look forward

University of London

At recent examinations the following were successful

D M R

L S Carstairs, R C M Hadden, G M Ross and D W Seth Smith

National University of Ireland

Dr Martin Folan has been appointed lecturer in clinical pathology at University College, Cork

Beit Memorial Fellowships for Medical Research

Dr A N Drury, F R S, has been appointed to the advisory board of the trust in place of the late Prof A J Clark Out of the 28 present Beit fellows 14 have now been seconded for whole time war work At a recent meeting of the trustee the following were elected

FOURTH YEAR FELLOWSHIPS

E G L Bywaters, MB Lond To continue his studies of crush injuries in relation to kidney function At the British Postgraduate Medical School, London

JUNIOR FELLOWSHIPS

D Herbert, PhD Camb To study the biochemistry of toxoids for active immunisation against gas gangrene At the Dunn Biochemical Laboratory, Cambridge University

F W Landgrebe, DSc Aberd To study the separation of po terior pituitary hormones, and their clinical uses At the medical school, University of Aberdeen

---

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

When the dosage is taken into account, the range of variation of the drug in the blood found in published studies is very similar to that recorded here. The figures of Kinsman and his colleagues (1939) for sulphapyridine are definitely lower on the average than ours They used an initial dose of either 2 or 4 g followed by 1 g four-hourly, and the slightly lower initial dosage may partly explain their lower values for the drug in the blood Also, their technical methods were likely to give rather low results

Brown and his colleagues (1939) found, as we do, that with maintenance doses of 6 g of sulphapyridine per day the level of the drug in the blood either rises or remains approximately steady Barnett and his colleagues (1939), using doses of sulphapyridine higher than ours in relation to body-weight, reported either accumulation or steady maintenance of blood sulphapyridine Volini and his colleagues (1940), comparing sulphapyridine with sulphathiazole at a dosage roughly the same as the lower dosage of our series, found, as we do, that the concentration of the drug in the blood is less well maintained with sulphathiazole than with sulphapyridine A similar tendency to falling levels on a dose of 6 g sulphathiazole daily is seen in the data of Sadusk and his colleagues (1940) and Finland and his colleagues (1941), and the fact that the concentration of the drug in the blood is lower with sulphathiazole than with sulphapyridine is shown also in the results of Flippin and his colleagues (1941) and Kinsman and Moore (1941) Data for sulphapyridine only are also given by Cullen and Wilson (1940), Flippin and others (1939), Ratish and others (1940), Finland and others (1940), and Abernethy and others (1939), and for sulphathiazole only by Gaisford and Whitelaw (1940), Callomon and Goodpastor (1940) and Scott and Jones (1940)

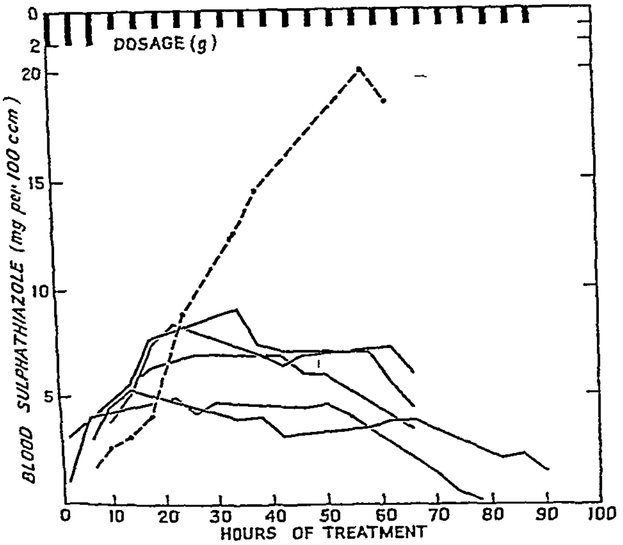

Fig 2—Blood sulphathiazole during treatment The dotted line shows the results for an old man who died

In our series only the free drug in the blood has been estimated As regards the bactericidal effect, only the free drug is concerned, but from the standpoint of toxicity the acetyl derivatives ("conjugated" drugs) ought also to be considered It was shown by Marshall and his colleagues (1938) that the acetyl derivative of sulphapyridine is as toxic as the free drug In the case of sulphapyridine, a large proportion of the total drug in the blood may be conjugated, and the conjugated form tends to accumulate with continued treatment (Brown et al 1939, Ratish et al 1940) Sulphathiazole is conjugated to a less degree than sulphapyridine in animals (Van Dyke et al 1939, Long et al 1940) The results of Sadusk and his colleagues (1940) and Strauss and his colleagues (1941) indicate the same in human subjects, but according to Flippin and his colleagues (1941) there is little difference between the two drugs on the average, though with sulphapyridine the proportion of the drug found in the conjugated form is more variable than with sulphathiazole Kinsman and Moore (1941) found a slightly greater degree of conjugation with sulphathiazole than with sulphapyridine, but in their results there was no undue accumulation of the acetyl derivative with either drug On the whole, it seems that there is somewhat less risk of accumulation of the acetyl derivative when sulphathiazole is used

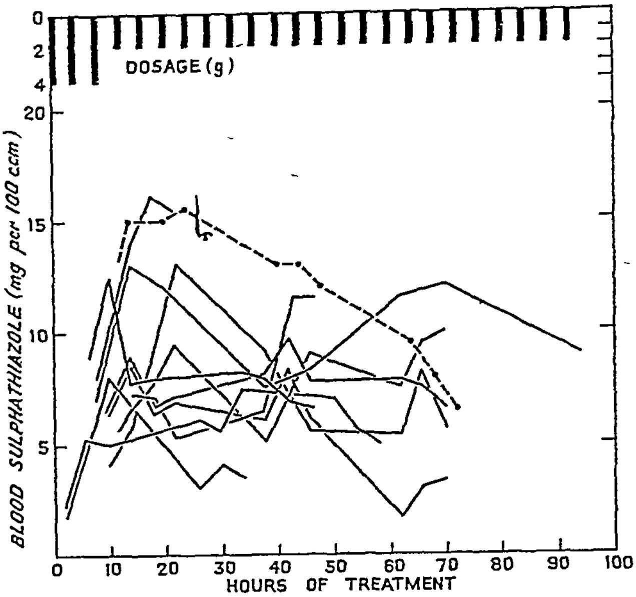

Fig 3—Blood sulphathiazole during treatment The dotted line refers to a patient who received 4 g instead of 2 g at the fourth dose

As regards the bactericidal effect, Long and Bliss (1940) found that the action of sulphathiazole was equal to that of sulphapyridine at the same concentration when tested on the pneumococcus in vitro It is difficult to determine with certainty what concentrations in the blood are required for the best therapeutic result Most observers consider that 6 mg per 100 c cm is adequate We regularly obtained higher values than this by giving three initial doses of 2 g sulphapyridine, followed by 1 g four-hourly With the same dose of sulphathiazole, 2 out of 6 cases failed to reach this level, and even in the group taking double the dose of sulphathiazole there were instances of failure to maintain a level of 6 mg per 100 c cm or more consistently

It is difficult to say whether it is an advantage to produce levels much above 6 mg per 100 c cm. In our short series of cases we found no correlation between the concentration of the drug in the blood and the rate of defervescence Callomon and Goodpastor (1940) and Flippin and his colleagues (1941) studied larger numbers and also found no advantage from the higher concentrations But this method of analysing the results is open to the objection that high blood levels are likely to be most frequent in patients with damaged kidneys, so that when the cases are classified according to the blood analyses the groups with higher figures are likely to include a higher proportion of patients gravely ill

In comparing the clinical results with the two drugs, the best evidence is given by the work of those who have used both drugs over the same period, since the results are not then affected by variations in the severity of the disease in different epidemics Such a comparison has been made by Volini and his colleagues (1940), who treated 164 patients with sulphapyridine and 169 with sulphathiazole, by Finland and his colleagues (1941), who treated 518 patients with sulphapyridine and 169 with sulphathiazole, by Flippin and his colleagues (1941), who treated 200 patients with sulphapyridine and 200 with sulphathiazole, and by Long and Haviland (1940) In these studies there was some difference in the intensity of the initial dosage, the total dose in the first 24 hours ranged from 7 to 12 g, but all used a maintenance dose of 1 g four-hourly in the succeeding period Under these conditions there was no significant difference between the two drugs as judged by mortality rates Flippin and his colleagues reported more rapid defervescence with sulphapyridine than with sulpha-

BLOOD CONCENTRATIONS OF THE DRUGS

Results for 13 patients treated with sulphapyridine are shown in table II and fig 1 There was a slight variation from the standard dosage in some cases , 7 received three initial doses of 2 g followed by 1 g four-hourly (fig 1) Of the remainder, 4 had only two doses of 2 g at the beginning, and 2 had four doses of 2 g All are included in fig 1, but the groups are separated in table II The two lowest concentrations of the drug in the blood were found in patients who received only the two initial doses of 2 g , but apart from this the variations did not seem to be related to the intensity of the early dosage, and the group may therefore be considered as a whole Individual variation in the concentrations reached with the same dosage was wide, but the characteristic result is a steep rise of the drug in the blood during the first twenty hours, and a more gradual rise later Some cases showed a more or less steady plateau in this later period , only a few showed falling levels on a maintenance dose of 1 g four-hourly The results shown in table II and fig 1 refer only to the period during which the stated dosage was maintained, but further analyses were made after reduction of the dose in some cases In these treatment was omitted during the night this always resulted in a fall of the concentration of the drug in the blood

TABLE II—RESULTS IN 13 PATIENTS TREATED WITH SULPHAPYRIDINE

Drug	Dosage (g)	Cases	Free drug in blood at			
			18–22 hr	42–46 hr	66–70 hr	90–94 hr
			mg per 100 c cm			
Sulphapyridine	221111	4	2 4–10 3	4 6–12 6	4 4–16 0	
	222111	7	6 1–15 3	11 5–13 5	10 0–20 7	8 0–15 5
	222211	2	6 5–10 7	8 8– 9 4	8 1–11 2	9 4–18 0
	Mean of all cases		9 0	11 2	12 2	13 0
Sulphathiazole	222111	(a) 1*	4 1–8 3	14 0	18 6	
		(b) 5	4 9–8 3	3 1–6 7	3 4–6 0	
	Mean for group (b)		6 5	5 5	4 0	
Sulphathiazole	444222	10	6 3–15 5	5 5–11 5	3 0–12 0	
	444422	1	15 0	13 0	8 0	
	Mean		8 5	8 1	7 8	

* A fatal case (elderly patient)

The first 6 patients treated with sulphathiazole received three initial doses of 2 g followed by 1 g four-hourly, and the results in this group are therefore strictly comparable with those for the group treated with sulphapyridine Of these 6 cases, 5 showed results which may be taken as characteristic (table II and fig 2) The concentration of the drug in the blood rose during a period ranging from fourteen to thirty-four hours, reaching a peak of 5–9 mg per 100 c cm , and then gradually falling The results are in striking contrast with those obtained for sulphapyridine , the maximum concentrations reached are lower, and with the maintenance dose of 1 g four-hourly the blood sulphathiazole falls, whereas with the same dose of sulphapyridine the blood sulphapyridine usually continues to rise

The sixth case in this group (the fatal case mentioned) shows a quite different result the blood sulphathiazole rose rapidly and continuously, reaching 20 mg per 100 c cm just before the patient's death This accumulation of the drug in the blood may have been due to renal insufficiency, but we have no evidence on this point It is impossible to say whether the high concentration of the drug in the blood contributed to the fatal result, or whether the accumulation of the drug was merely an incidental effect of the patient's condition

When it became evident that the dosage of sulphathiazole used for these first 6 cases was not producing such high concentrations in the blood as were obtained with the same doses of sulphapyridine, it was decided to double the dosage for the remainder of the patients treated with sulphathiazole ; 10 patients received the higher dosage, namely, three initial doses of 4 g followed by 2 g four-hourly (table II and fig 3) There is great individual variation both in the maximum levels of the drug in the blood, and in the form of the curve obtained when the concentrations of the drug in the blood are plotted against the duration of treatment The initial rise of the drug in the blood is steep , a peak is reached early, often in less than ten hours After the early peak the level falls, usually quite steeply Some cases show a secondary rise beginning after about thirty-eight hours of treatment Although this group of patients received the higher dosage, they show distinctly lower levels of the drug in the blood than the patients receiving sulphapyridine in lower dosage, except in the earliest stage of the treatment Moreover, the steady accumulation of the drug in the blood often found with a maintenance dose of 1 g sulphapyridine four-hourly is not found with double the dose of sulphathiazole

The results given in table II and fig 3 are those found during the period of the standard dosage In 7 of the cases further blood analyses were made after reduction of the dose, either by omission of the night doses (2 cases) or by reduction from 2 g to 1 g four-hourly Reduction by either method caused a fall in the concentration of the drug in the blood , this confirmed the earlier observation that 1 g of sulphathiazole four-hourly is not sufficient to maintain a steady level of the drug in the blood

DISCUSSION

Like other workers, we have found great variation in the concentrations of free sulphapyridine or sulphathiazole in the blood of patients treated with the same drug in the same dosage This is not surprising, as variations in the rate of absorption and excretion are to be expected in patients who are severely ill But in spite of the individual variation, it has been shown that both sulphathiazole and sulphapyridine in the blood rise rapidly under the treatment to effective therapeutic levels, though these levels are much less readily maintained with sulphathiazole than with sulphapyridine The curves shown (figs 1–3) strongly suggest that sulphathiazole is absorbed as rapidly as sulphapyridine but is more rapidly excreted We have made no analyses of the drugs in the urine in our cases, but the work of others has shown that sulphathiazole is more rapidly excreted than sulphapyridine both in animals (Van Dyke *et al*, 1939) and man (Spink and Hansen 1940, Strauss *et al* 1941, Kinsman and Moore 1941)

Reports on the concentrations of sulphapyridine and sulphathiazole in the blood of patients under treatment have been made recently by others, and there are data available for large numbers of cases studied at different stages of treatment On the whole the early period of treatment has been more fully studied than the later stages, and although all stages are represented there are not many records of the changes in concentration of the drug in the blood in the same patients throughout the treatment

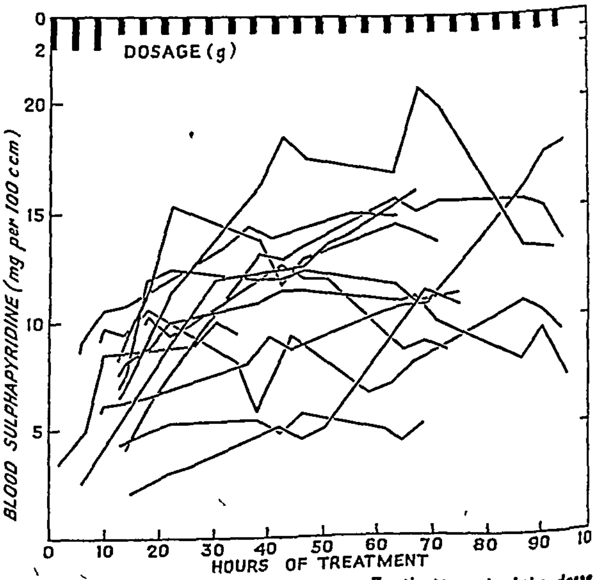

Fig 1—Blood sulphapyridine during treatment 7 patients received the dosage shown , 4 had 1 g instead of 2 g at the third dose , two had 2 g instead of 1 g at the fourth dose

1,960,000; Hb 50%, colour-index 1 3, white cells 11,200, normal differential count red cells irregular in shape and size, normoblasts numerous, with some megaloblasts, myeloblasts and punctate basophilia; reticulocytes under 1% of red cells Free acid in normal amount in gastric juice Pyrexia continued for a few days Given diet rich in protein, with half a pound of liver each day, and 'Ventriculin (PDCo) 1 vial t d s She improved very much both clinically and hæmatologically, and by the following August felt quite well and had a normal blood count All specific treatment was discontinued

She has been seen from time to time (last, in September, 1941), and has kept well with a normal blood-count No further pregnancy

CASE 2—Age 27 A hawker. Always healthy Three normal pregnancies and confinements Fourth child born on May 18, 1934; well during this pregnancy No antenatal care, normal confinement no undue blood loss Pallor noticed directly after confinement On admission to hospital on the same day she was extremely ill with well marked pallor and pyrexia Red cells 925,000, Hb 30%, CI 1 16; halo 8 19 μ, white cells 10,400. normal differential count, red cells irregular in shape and size; megaloblasts and many normoblasts seen, reticulocytes under 1% Free acid in gastric juice was below normal Well marked periostitis of the tibiæ, Wassermann and Kahn reactions strongly positive 'Hepatex' (Evans) 5 c cm given intramuscularly each day for a week and then hog s stomach 2 dr t d.s. Pyrexia disappeared; blood value quickly increased All specific treatment was then discontinued

In August. 1941, she replied to a questionnaire that both she and the child had been quite well since she left hospital, she had had no further pregnancies She did not submit to antisyphilitic treatment which was advised

CASE 3—Age 37 Had had 5 children, normal pregnancies and confinements Health always good Last child born July 16, 1935 Some swelling of feet during last three months of this pregnancy Had antenatal care No undue blood loss Since confinement, increasing weakness, breathlessness, swelling of feet. pallor and soreness of tongue Admitted to hospital Oct 23, 1935, extremely ill Very pale with slight icteric tinge of the skin, much glossitis, numbness and paræsthesia of forearms and hands, but nothing objective found in the rest of the nervous system, except retinal hæmorrhages Spleen just palpable Red cells 750,000, Hb 19% CI 1 2, white cells 5600; normal differential count, many nucleated red cells, considerable anisocytosis, poikilocytosis and polychromasia, reticulocytes under 1% of the red cells. Complete absence of free acid from gastric juice Child healthy with no sign of anæmia Patient was transfused, and hepatex (2 c cm) was injected intramuscularly each day Good reticulocyte response Patient's condition began to improve and temperature to settle, in a month's time blood-count had become normal. A second test-meal showed a normal amount of free acid Specific treatment discontinued.

Both she and the child remained well In 1936 she again became pregnant She remained well with a normal blood-count, hepatex, 2 c cm, was given once every two weeks as a prophylactic In October she was delivered of a healthy child, normal pregnancy and puerperium Another child was born in 1940 with no ill effect on her health No specific treatment given during this pregnancy Last seen in 1941, health then good and blood still normal.

CASE 4—Age 33 Health had always been good First child born Dec 31, 1934 Healthy pregnancy with antenatal care and a normal confinement Afterwards she was weak and pale with shortness of breath and lemon coloration of the skin On admission to hospital on Feb 4, 1935, she was very ill with high pyrexia Petechial hæmorrhages into the skin, hæmorrhages into both retinæ, and glossitis Red cells 730,000, Hb 24%, CI 1 6, halo 7 6 μ, white cells 6400, differential count normal, red cells very irregular in shape and size with polychromasia and megalocytosis. reticulocytes 1 5% of the red cells, platelets 80,000, fragility of red cells not increased Van den Bergh reaction was practically negative No free acid found in gastric juice Hepatex, 5 c cm at first intravenously and then intramuscularly, given each day Brisk reticulocyte response General condition improved and by the end of March, when she left hospital blood was normal A test-meal showed normal acidity The baby was healthy

Her doctor reported in September, 1941, that she had remained well without any specific treatment No further pregnancy

CASE 5—Age 32 Had always been healthy Normal pregnancy and puerperium with the first child Second child born April 6, 1937 During the last weeks of this pregnancy pale with increasing weakness and shortness of breath, much vomiting and taking little food On admission to hospital on April 10 she was extremely ill Red cells 1,150,000, Hb 23% CI 1 1, halo 7 4 μ; white cells 12,000 normal differential count, red cells irregular in shape and size, with 400 normoblasts per c.mm, and punctate basophilia, reticulocytes under 1% Van den Bergh test gave a faintly positive indirect reaction Small amount of free acid in gastric juice Two blood-transfusions given at short intervals and hepatex, 4 c cm injected each day By the end of July blood was normal All specific treatment then discontinued Child healthy

Since then the patient has remained well with a normal blood-count No further pregnancy

CASE 6—Age 33 Had always been well. Normal first pregnancy until the last two months, when she began to be short of breath, Normal confinement on Dec 16, 1938 No undue loss of blood. Manual removal of placenta Increased pallor and pyrexia after delivery On admission red cells 2,000,000, Hb 42%, CI 0 91 white cells 6300, differential count normal poikilocytosis, anisocytosis, normoblasts and megaloblasts seen, reticulocytes under 1% Test-meal showed free acid though in diminished amounts Child was healthy Hepatex 4 c cm, given each day intramuscularly, satisfactory reticulocyte response Blood-count rose to full value Specific treatment then discontinued

She has remained well with a normal blood count No further pregnancy

CASE 7—Age 31. First child, normal pregnancy and puerperium Good health until the second pregnancy Husband out of work, food at home especially meat, had been short For the last two months of the pregnancy she had been short of breath, weak and pale, and was treated for toxæmia of pregnancy by being kept in bed on a milk diet Normal confinement on May 1, 1941 Then condition suddenly became worse Faint icteric tinge of the skin Red cells 650,000, Hb 24%, CI 1 8; white cells 6500; halo 7 8 μ poikilocytosis, polychromasia and anisocytosis. normoblasts 180 per c.mm, reticulocytes 1% of red cells Test-meal showed free acid but in diminished amount Hepatex, 4 c cm given intramuscularly each day. Satisfactory reticulocyte response Blood value rose and general condition improved Specific treatment then discontinued

When last seen in September, 1941 she had been well since leaving hospital No further pregnancy Child had remained well

CASE 8—Age 29 Five normal pregnancies Had always been well Became pregnant again in May, 1941. After the first month undue tiredness and lack of energy. Miscarriage on Sept 4, no undue hæmorrhage Became very pale and short of breath directly afterwards Red cells 2,100,000; Hb 45%; CI 1 09 white cells 5300, normal differential count, well-marked anisocytosis and poikilocytosis, normoblasts 100 per c.mm, reticulocytes under 2%, platelets diminished Test meal showed normal acidity Brisk reticulocyte response followed daily injections of 4 c cm of hepatex. Rapidly improved When her blood-count became normal specific treatment was discontinued She remains well

CASE 9—Age 28 Had always been well until the last two months of the second pregnancy, when the legs swelled and she became somewhat weak and pale Normal confinement on Aug 30 1941 No undue blood loss Child healthy Admitted to hospital a month later as symptoms had become worse Glossitis and well-marked retinal hæmorrhages Red cells 2,100,000, Hb 40%, CI 0 95 white cells 5300 normal differential count, anisocytosis and poikilocytosis, normoblasts 50 per c.mm, platelets diminished Biopsy of bone-marrow showed increased cellularity with megaloblastic hyperplasia Acid in gastric juice below normal Hepatex, 4 c cm, injected intramuscularly each day. Brisk reticulocyte response followed Improved clinically and hæmatologically By November the blood was normal and specific treatment was discontinued A second test-meal showed a normal amount of acid. She remains well

COMMENT

Pernicious anæmia of pregnancy usually occurs in multiparæ generally in the middle or later years of thiazole Garvin (1940) also compared the two drugs, treating 40 patients with sulphathiazole and 62 with sulphapyridine He recognised that it was necessary to use a higher dosage of sulphathiazole than of sulphapyridine in order to get approximately comparable concentrations of the drug in the blood For sulphapyridine he used one initial dose of 2 g followed by 1 g four-hourly, and for sulphathiazole one initial dose of 4 g followed by 2 g four-hourly There was no significant difference in the fatality-rates in the two groups, but there was more rapid defervescence with sulphapyridine than with sulphathiazole Wagoner and Hunting (1941) used sulphapyridine and sulphathiazole in the treatment of pneumonia in children They aimed at a concentration of 4–6 mg per 100 c cm in the blood, adjusting the dosage as required The two drugs were equally effective.

Evidence of the incidence of toxic effects for both sulphapyridine and sulphathiazole has been given by Flippin and his colleagues (1940, 1941), Finland and his colleagues (1941), Garvin (1940), Wagoner and Hunting (1941), and Kinsman and Moore (1941) For sulphapyridine only, the toxic effects are analysed also by Finland and his colleagues (1940), and for sulphathiazole only by Volini and his colleagues (1940), Reinhold and his colleagues (1940), Pepper and Ham (1940), Spink and Hansen (1940), Scott and Jones (1940), and Callomon and Goodpastor (1940) Taking all these results together, the most striking difference is the much greater incidence of nausea and vomiting with sulphapyridine The rarer toxic effects—damage to the kidneys, damage to the hæmopoietic tissues, drug rashes, drug fever and mental symptoms—are all slightly commoner with sulphapyridine than with sulphathiazole However, most of these observers used the two drugs at approximately the same dosage, so that the average concentration of the drug in the blood would be lower in the groups treated with sulphathiazole Garvin's series, in which the dosage of sulphathiazole was double that of sulphapyridine, also showed a higher incidence and greater severity of vomiting with sulphapyridine than sulphathiazole There was little difference in the incidence of dermatitis (though there were too few cases of dermatitis in either group for a true comparison) Crystals of the drug in the urine were found much more often with sulphathiazole than with sulphapyridine, and microscopic hæmaturia was rather commoner with sulphathiazole Wagoner and Hunting (1941) found vomiting commoner with sulphapyridine than sulphathiazole, although they adjusted their dosage to get similar concentrations of the drugs in the blood

In conclusion, it is evident that in order to get the same concentration of the drug in the blood, sulphathiazole must be used in much higher dosage than sulphapyridine With sulphathiazole, the maintenance of an effective blood level is more difficult, and it depends on a balance whereby greater amounts are absorbed and excreted than with sulphapyridine , hence there may be a greater danger of crystallisation of the drug in the kidneys when sulphathiazole is used Also, it becomes more important to check the progress of the treatment by blood analyses when sulphathiazole is used, in order to avoid excessive retention of the drug if the kidneys are damaged The only advantage of sulphathiazole seems to be a less tendency to cause vomiting, but even this advantage is less striking in the experience of workers who increased the dosage of sulphathiazole in order to compensate for its more rapid excretion

SUMMARY

Sulphapyridine has been compared with sulphathiazole in the treatment of 30 cases of lobar pneumonia

The concentrations of free sulphapyridine and free sulphathiazole in the blood of the patients have been followed throughout the course of treatment

Effective concentrations of the drug in the blood are much more readily maintained with sulphapyridine than with sulphathiazole, and this is explained by the more rapid excretion of sulphathiazole

The present series is too short for an adequate evaluation of clinical results, but recent reports on much larger numbers are reviewed, and it is concluded that sulphathiazole has no advantage over sulphapyridine as a chemotherapeutic agent Sulphathiazole has less tendency to cause vomiting

We wish to thank Dr J A Charles, medical officer of health to Newcastle on-Tyne, for giving us the opportunity to investigate patients at the Newcastle General Hospital and the City Hospital for Infectious Diseases, and Messrs May and Baker for supplies of sulphapyridine ('M & B 693') and sulphathiazole ('M & B 760')

THE GRAVE ANÆMIAS IN PREGNANCY AND THE PUERPERIUM

REPORT OF 17 CASES

F Graham Lescher, M C , M D CAMB , M R C P
PHYSICIAN TO DERBYSHIRE ROYAL INFIRMARY AND GENERAL INFIRMARY, BURTON ON TRENT

In the last few years an increasing number of cases of grave anæmia of pregnancy have been reported, but the condition is uncommon Full reviews of this subject have been given by Wilkinson (1932), Whitby (1932), Witts (1932), and by Stevenson (1938), who, during 1928–34, studied 30 cases, the largest number reported by any one observer

During 1934–41 I have studied and followed up 17 patients suffering from grave anæmias of pregnancy These fall into two groups cases 1–9 are of the pernicious variety , cases 10–17 belong to the hæmolytic group In each patient a critical search was made to exclude infection, carditis, nephritis and other diseases which could possibly have been factors in the production of a severe anæmia

Temporary Pernicious Anæmia of Pregnancy

In order to save space, only positive clinical findings are given Intermediate blood and other reports are omitted Fresh blood was used for all transfusions, from donors of the same group as the patients , cross matching was performed in every case No difficulty was experienced in grouping The blood was always given slowly by the drip method, and no abnormal reaction ever followed

Case 1—Age 31 Two former pregnancies Pyelitis during the first , second normal Otherwise healthy In May, 1933, she again became pregnant Much vomiting November, premature delivery of stillborn twins No undue hæmorrhage or other complications Since then increasing weakness, breathlessness and pallor On admission to hospital on May 14, 1934, she was very ill Slight lemon yellow tinge of skin , glossitis , spleen palpable Red cells

When last seen in September, 1941, her health had remained good and there was no anæmia. No further pregnancy.

CASE 17.—Age 34. Had always been well. First pregnancy and confinement on Feb. 22, 1941, was normal. Directly afterwards she became weak, short of breath and pale, with an icteric tinge. Red cells 500,000; Hb 30%; CI 1·0; halo 8·0 μ; poikilocytosis and polychromasia; normoblasts 230 per c.mm.; reticulocytes 12%; platelets not reduced; fragility of red cells normal. Strongly positive indirect van den Bergh reaction. Injections of liver extract given each day. She improved and left hospital with red cells 3,750,000; Hb 60%; white cells 5800; no abnormal red cells; reticulocytes 4%. The child was well.

No reply was received to a questionnaire sent in September, 1941.

COMMENT

It has already been pointed out (Lescher and Osborn 1939) that the hæmolytic anæmias form a somewhat unsatisfactory group, since there is actually no very clear and accepted standard as to what constitutes clinical hæmolysis. Even when its existence is accepted there is seldom direct evidence of it (such as hæmoglobinæmia, hæmosiderinuria and the presence of ghost cases) since it occurs rarely in the blood-stream itself. Acute hæmolytic anæmia occurs, of course, in conditions other than pregnancy. There is no evidence that a hæmolysin ever develops in the maternal or fœtal structures. Neither nutritional and digestive defects nor infection seem to play any part in its production.

Prognosis, Treatment and Differentiation

Patients with these grave anæmias of pregnancy should not be allowed to drift in the hope of spontaneous cure; for the old belief that a cure results after delivery without specific treatment, is without foundation. For example, cases 1, 10, 12, and 13 were very ill for some months after confinement, and no improvement took place until specific treatment was started. Before the renaissance in the treatment of Addison's anæmia the maternal mortality of patients suffering from temporary pernicious anæmia of pregnancy was high, and so was the fœtal death-rate. Now with accurate diagnosis and adequate treatment, the prognosis has much improved. In the 9 cases reported here the maternal death-rate was nil. In cases 1 and 8 the children were stillborn. There is no reliable evidence that the children inherit either type of anæmia.

Temporary pernicious anæmia of pregnancy will respond well to adequate treatment with liver preparations, although Davidson has called attention to similar cases who were refractory to this treatment; and there is a reasonable chance of the patient bearing a healthy child. This treatment should be continued until the blood is normal and the pregnancy over, after which it can be discontinued, since in this type of anæmia, unlike Addison's anæmia, relapses will not occur. If the anæmia is due to the absence from the diet of extrinsic factor (as it may have been in cases 1, 5 and 7), the addition of meat protein or 'Marmite' to the diet, or treatment with liver, should bring about improvement. Blood-transfusions were resorted to as an emergency measure in cases 3 and 5, because these patients were very ill; but with a better knowledge of the efficiency of liver treatment these may have been unnecessary.

While the ætiology of Lederer's anæmia remains unknown treatment must necessarily be empirical. Patients often react dramatically, especially after parturition, to a blood-transfusion, repeated if necessary. Even though some of these patients were desperately ill, they all recovered with the exception of one (case 15), and she was moribund on admission to hospital. Case 14 did not respond quickly, possibly because of the coincident sepsis. It is true that liver and iron were given to several of the patients reported above, together with blood-transfusions. But in cases 10, 11 and 13 liver and iron and a generous diet were used for several months with no improvement until treatment with blood-transfusions was started; in case 17, it is true, recovery followed the use of liver alone.

Patients suffering from either of these grave anæmias, when treated promptly and energetically, may be allowed to go to term, and there is a reasonable chance of the patient bearing a healthy child. A critical review of published work supports, on the whole, the view that these anæmias, especially the pernicious variety, may recur in subsequent pregnancies; but with suitable antenatal supervision, including blood-examinations, the necessary treatment can be given early, so that these patients should be able to complete their pregnancies successfully. In this series only 2 patients became pregnant subsequently. There was no return of the anæmia.

From the history and clinical signs alone a differential diagnosis cannot be made with certainty between temporary pernicious anæmia and hæmolytic anæmia, save that in most cases of the hæmolytic type in the above series the patient had an icteric colour as compared with the slightly lemon tinge seen in the patients with pernicious anæmia. Glossitis was found in 4 of the temporary pernicious anæmia cases whereas it occurred in only 1 suffering from the hæmolytic type. With both varieties the anæmia was severe, and most of the cases were of the megalocytic type. The red cells showed considerable irregularity in size and shape, with normoblasts and occasionally punctate basophilia. Megaloblasts were rather more prominent in the hæmolytic type. No spherocytosis was seen. Estimation of the fragility of the red cells was of no help.

The main differentiating points found in the blood examinations were three. First, in the hæmolytic type of anæmia not under specific treatment, the percentage of reticulocytes was always much raised; this was so in every case in the series. In temporary pernicious anæmia, however, these cells were not increased unless liver had been given recently, and even then the rise was not sustained for longer than a few days; all the cases of temporary pernicious anæmia in which this test was tried gave a typical reticulocyte response followed by a rise in the number of the red cells. Secondly, in temporary pernicious anæmia the serum bilirubin is within normal limits or only slightly raised, and there is only a faint indirect van den Bergh reaction. In the hæmolytic type, however, since the anæmia is caused by hæmolysis of the red cells with the liberation of hæmoglobin, the serum bilirubin is naturally increased and there is a strongly positive indirect van den Bergh reaction. Had more samples of bone-marrow been obtained by sternal puncture, they would no doubt have provided information useful in differentiating these two types of anæmia. One would have expected, in the pernicious type, a mixed erythroblastic reaction with great increase in the number of megaloblasts; whereas in hæmolytic anæmia, although there are signs of great marrow activity, the hyperplasia is normoblastic in type (cases 9 and 15). Thirdly, the two varieties of anæmia react differently to specific remedies: liver extract given parentally in large doses will raise the level of the blood to normal in temporary pernicious anæmia, but it will not have this effect in the hæmolytic type occurring during pregnancy—for such cases blood-transfusions are necessary.

SUMMARY

A series of 17 cases of grave anæmia associated with pregnancy has been reported; 9 with temporary pernicious anæmia and 8 hæmolytic anæmia (Lederer).

In 8 cases the symptoms and signs of the anæmia started before delivery, generally in the last 3 months of pregnancy, and progressed generally rapidly, after parturition. In the remainder the anæmia developed suddenly, often dramatically, after the confinement.

No patient had received adequate antenatal supervision and treatment. No blood-examinations had been made before admission to hospital; increased facilities for blood-examinations during pregnancy are needed.

It is important to determine the type of anæmia before beginning treatment. There is a specific treatment for each of the types of anæmia described, which if given early should much reduce the maternal and fœtal mortality.

With adequate antenatal supervision, including blood-examinations, a woman who has previously suffered from one of these grave anæmias should be able to undergo subsequent pregnancies successfully.

My thanks are due to Mr N. Edwards for permission to study several of the patients who were admitted under his care.

References at foot of next page

reproductive life In this series the average age was 31 years The early signs are often insidious, appearing usually during the last three months of pregnancy, they may easily be missed Some patients go through pregnancy without serious inconvenience In others, the anæmia develops suddenly, often dramatically, soon after delivery (cases 2, 3, 4 and 6) The symptoms, signs and changes in the blood are similar to those found in Addison's anæmia In the pernicious anæmia of pregnancy, however, the mean diameter of the red cells may approach more to normal, and there is as a rule no leucopenia There are no signs of hæmolysis The bone-marrow is similar in both diseases, but in pernicious anæmia of pregnancy, unlike Addison's anæmia, no organic lesions of the brain or spinal cord have been reported except in one case (Strauss and Castle 1933), though mild paræsthesias are occasionally found (case 3) Severe antepartum or postpartum hæmorrhage and sepsis are as a rule remarkable by their absence

The similarity of Addison's anæmia to this temporary pernicious type and the fact that in the latter there is often a derangement of gastric function, shown by the diminution or absence of hydrochloric acid in the test-meal, suggest that an analogous mechanism is likely to be involved (Strauss and Castle 1933) In the cases reported here, hydrochloric acid was found in normal amounts in only 2, in 2 it was absent and in 5 deficient in amount Deficiency of extrinsic factor in the diet might have been responsible, at any rate partially, for the anæmia in some patients (cases 1, 5 and 7) After delivery the level of the acid may rise to normal (cases 3, 4 and 9)

Acute Hæmolytic Anæmia of Pregnancy

The following 8 patients were found to be suffering from acute hæmolytic anæmia, of the type described by Lederer (1930)

Case 10—Age 28 Shortness of breath and unusual pallor towards end of first pregnancy Normal confinement on May 12, 1939 Child healthy No undue blood loss Symptoms became worse in spite of treatment with liver and iron Admitted to hospital on July 7 Very ill with pyrexia, icteric tinge of the skin and glazing of the tongue Red cells 1,500,000, Hb 35%, CI 1 2, halo 7 6 μ, red cells irregular in shape and size with many normoblasts and megaloblasts, reticulocytes 10% of red cells, platelets not reduced Strongly positive indirect van den Bergh reaction Normal acid in gastric juice A course of hepatex, 4 c cm, intramuscularly each day and several blood-transfusions given Condition improved and pyrexia disappeared Blood value rose to normal

When last seen in September, 1941, her health had remained good There had been no further pregnancy

Case 11—Age 30 Three children Pregnancies and confinements normal Health good until pleurisy during the seventh month of the fourth pregnancy Progressive weakness, pallor and shortness of breath since Normal confinement on Nov 25, 1938 Child healthy In spite of repeated injections of liver her condition deteriorated, and she was admitted to hospital on Feb 3, 1939, extremely ill Red cells 1,200,000, Hb 20%, CI 0 83, poikilocytosis, anisocytosis and polychromasia well marked, megaloblasts and normoblasts present, reticulocytes 15% of red cells, mean corpuscular thickness normal, no spherocytes seen, fragility of red cells slightly increased Indirect van den Bergh reaction present Test meal showed no free acid Three blood transfusions given, with liver extract and iron A month later her condition had vastly improved Red cells 3,500,000, Hb 70%, no immature cells seen

She has remained well with a normal blood count and without any specific treatment No further pregnancies

Case 12—Age 35 Normal first pregnancy and confinement on Feb 16, 1939 No antenatal care No undue blood loss Since then, pale, weak and short of breath, with pyrexia and an icteric colour Red cells 1,200,000, Hb 25%, CI 1 04, halo 7 6 μ, white cells 13,000, normal differential count, well marked anisocytosis, poikilocytosis and polychromasia, normoblasts, stippling of red cells and myelocytes, reticulocytes 20% of red cells, platelets 250 000, fragility of red cells normal Hydrochloric acid in normal quantities in the test meal She improved after treatment with several blood-transfusions Pyrexia diminished, blood increased in value and reticulocyte count diminished The child remained well

In September, 1941, she replied to a questionnaire that her health had remained good Another healthy child was born in June, 1941 No antenatal care Normal pregnancy and confinement

Case 13—Age 35 Second child born Nov 29, 1938 Normal pregnancies and confinements No undue blood loss No antenatal care Lost energy and became short of breath and increasingly pale directly after the second confinement Treated with large doses of liver, iron, vitamin C and a generous diet No improvement Admitted to hospital on June 29, 1939 Red cells 1,390,000, Hb 40%, CI 1 4, halo 8 3 μ, white cells 4000 with a normal differential count, red cells irregular in shape and size, with many normoblasts and megaloblasts, reticulocytes 15% of red cells, platelets 405,000, strong indirect van den Bergh reaction Normal amount of free acid in gastric juice Several blood transfusions given She left hospital well with a normal blood count

In September, 1941, she replied to a questionnaire that she and the child had remained well No further pregnancy

Case 14—Age 20 Health good until a miscarriage in June, 1939, when three months pregnant No serious hæmorrhage Admitted to hospital a week later on account of abdominal pain and pyrexia A mass felt in the left fornix Normal red cell count with a leucocytosis of 21,000 per c mm Cultures from the cervix gave a growth of hæmolytic streptococci, but blood cultures made under aerobic and anaerobic conditions remained sterile The uterus was explored and she was given sulphanilamide 1 g 4 hourly for a week, and nursed in the fresh air Her condition deteriorated, blood-count started to fall and jaundice developed On July 30, red cells 1,340,000, Hb 37%, CI 1 4, halo 8 6 μ, red cells irregular in shape and size, normoblasts 2500 per c mm, megaloblasts present, reticulocytes 25% of the red cells, no spherocytosis or ghost cells seen Van den Bergh test showed a strongly positive indirect reaction Urine contained albumin and urobilin Liver and spleen enlarged Treated with blood transfusions, liver extract and iron Improvement and relapses followed In October she left hospital much improved, with a normal blood count

In September, 1941, in answer to a questionnaire, she replied that she had quickly regained her health after leaving hospital and had remained well No further pregnancy

Case 15—Age 29 Health had always been good Periods regular, the last being four weeks before admission On Feb 1, 1940, excessive vaginal hæmorrhage Rapidly became pale and jaundiced She lived in an isolated farm and owing to the depth of snowdrifts the doctor, after several attempts, could only reach her at the end of the second day With the greatest difficulty she was removed to hospital the next day and arrived in a state of extreme shock All bleeding had stopped Pallor and jaundice were severe, and in spite of resuscitation, including a blood transfusion, she died within a short time of admission A blood examination made shortly before death showed red cells 1,260,000, Hb 36%, CI 1 4, halo 8 0 μ, white cells 64,000, many normoblasts and megaloblasts, reticulocytes 30% of the red cells, platelets normal Strong indirect van den Bergh reaction

At autopsy the spleen was typical, histologically, of the kind seen in hæmolytic anæmia (Lescher and Osborn 1939), gross engorgement of the sinusoids, blood cells were being rapidly destroyed by the littoral cells, abundant hæmosiderin granules Bone marrow deep red and cellular, normoblasts predominated, though all the series were represented Acini and ducts of the breasts were distended with milk The cervix admitted the tip of the little finger No trace of placental elements found

Case 16—Age 24 Normal first pregnancy and confinement Jan 20, 1941 No undue hæmorrhage Child healthy Patient became pale and breathless soon after delivery, anæmic and jaundiced Pelvic cellulitis with swelling of the right leg Red cells 3,000,000, Hb 53%, CI 0 88, halo 7 8 μ, white cells 21,400, megalocytosis, anisocytosis and poikilocytosis, normoblasts 200 per c mm, with numerous reticulocytes, mean corpuscular thickness and volume increased Strongly positive indirect van den Bergh reaction Smears from cervix showed streptococci, but there was no growth Blood cultures negative Sulphanilamide treatment was started and she was given two blood transfusions In a fortnight she began to improve and the temperature fell She left hospital on March 3, much better with an almost normal blood count The child was well until tea-time. On being transferred to a smaller ward with better supervision and extra diet they improved and there was no further trouble. This is a point of some importance when large numbers of uncooperative patients are being treated.

TABLE I—RESULTS IN 200 CASES

Diagnosis	All cases		Recovered		Imp		Imp in hospital		Not imp	
	M	F	M	F	M	F	M	F	M	F

Total	200		59		23		29		89	

M and F = male and female. Imp = improved.

RESULTS

The results of treating 63 males and 137 females are shown in table I. Cases have been classified in 5 diagnostic groups, but in the schizophrenic and affective illnesses only are numbers large enough to allow conclusions to be drawn. Under the heading "depression" are grouped melancholias and depressions, including involutional melancholia from whatever cause, and depressive phases of the manic-depressive psychosis; the schizophrenic group has not been subdivided.

The criteria of results are four: complete remission of symptoms with the return of full working capacity; partial recovery sufficiently great to enable the patient to remain outside hospital; maintained improvement social or ideational in patients still hospitalised; no improvement. Of the 200 patients, 20 men and 62 women were discharged from hospital; of these 12 men and 47 women made a complete recovery and none of these have since relapsed. This represents a discharge-rate of about 40% of all patients treated, irrespective of the nature or duration of the mental illness. It will be seen however that this figure is chiefly determined for the better by the proportion of affective psychotics treated and for the worse by the schizophrenics.

Schizophrenia.—Of 114 schizophrenics of both sexes only 12 left hospital, 4 women alone being considered to have recovered. The remaining 102 required institutional supervision, but in 26 of these some degree of sustained benefit was observed. In other words, treatment of 114 patients has been justified by some improvement in 38 cases, of which only 4 showed full remission.

TABLE II—RESULTS IN SCHIZOPHRENIA

Duration of illness	All cases		Recovered		Imp		Imp in hospital		Not imp	
	M	F	M	F	M	F	M	F	M	F
Under 1 year	5	12	0	4	0	1	1	1	4	6
1–2 years	12	16	0	0	3	3	4	6	5	7
Over 2 years	24	45	0	0	0	1	5	9	19	35
Total	114		4		8		26		76	

It is debatable whether shock treatment of chronic schizophrenics is really worth while when allowance is made for spontaneous remissions. This becomes even more dubious when it can be reported that 2 schizophrenic women whose psychosis was quite unaffected by persistent shock therapy made spontaneous remissions several months later; one is now serving in the Forces and the other is almost fit to leave hospital. Moreover, 3 subjects, 2 women and 1 man who had been in hospital for upwards of six years failed to improve in any way with long courses of shock treatment, but have shown considerable and it seems increasing improvement after recent prefrontal leucotomy.

The duration of symptoms is usually taken into account in making a prognosis for shock therapy. Not all the recent cases of schizophrenia admitted to hospital were treated. A few were rejected on grounds of physical unfitness, permission for treatment was refused in 2, and as a small number were improving spontaneously it was not necessary to institute shock therapy. This explains the disproportionately small number of early cases in the series; the number treated who had been ill for less than a year is only 17. It is noteworthy that the only schizophrenics who recovered belonged to this group, and that the results of treatment are very much worse in illnesses of longer duration (table II). Nevertheless, since 13 out of 17 recent cases failed to improve at all it was not possible to make an optimistic prognosis in any clear-cut case of schizophrenia. No doubt some of the subjects classified in the mixed psychoses could be included with the schizophrenics, thereby influencing the results for the better.

On the whole, although this series contains a disproportionate number of chronic cases, it has been worth while treating schizophrenia in the hope of improvement without necessarily hoping for recovery.

Affective psychoses.—Of 64 patients with affective psychoses treated, 11 men and 46 women were discharged including 10 men and 39 women recovered; 2 men and 3 women failed to improve, 1 of each sex improved but still required hospital care because of the short periods of remission between maniacal phases. Most affective psychotics therefore recover or show much improvement with electrical shock treatment so that cases which fail to respond are of particular interest. In this series, of the 3 women, 1 had a temporary remission and relapsed; she now presents the clinical picture of Simmonds's disease. The second is an agitated melancholic with additional obsessional features whose symptoms have not altered for more than 10 years. The third was a reactive depressive who failed to improve with shock treatment, but afterwards made a spontaneous recovery when certain domestic and situational difficulties had been settled. One man suffering from recurrent mania relapsed repeatedly so long as certain psychogenic causes in his home existed. He later made a spontaneous recovery. One man with reactive depression failed to improve and later died of pneumonia. In his case external psychogenic factors were operating throughout.

Mode of recovery.—Where the affective reaction seemed to be endogenous, improvement appeared within the first two weeks of treatment; this was especially noticeable in involutional cases in which recovery was smooth and uninterrupted. Where there were external factors of psychogenic importance temporary relapses were common. It seemed to be a necessary part of treatment to settle the psychogenic situation if a lasting cure was to be expected. Two cases of depression accentuated by the fear of air-raids made an apparent recovery only to relapse after a few days at home. Both eventually left hospital after further courses of shock treatment, apparently cured at a time when air-raids were less to be expected. One woman whose husband deserted her failed to maintain her improvement until a settlement had been arranged between him and her family. Other cases could be cited in which disappearance of symptoms after a short course of shock treatment was not enduring so long as provoking factors remained outstanding. This appears to be of some importance in making a prognosis. In all psychoses the outlook is better where there is a strong affective element, for it is on affective disturbances that convulsive therapy seems to exercise the greatest influence. This was demonstrated in all the cases of schizophrenic and mixed psychoses that showed improvement.

SUMMARY AND CONCLUSIONS

Electrically induced convulsion therapy is a safe and convenient method of physical treatment in mental disorders. It is highly satisfactory in affective reactions and especially in involutional melancholia, but it cannot be regarded as a specific, and to be successful should be accompanied by psychotherapy on general lines. Its value in chronic schizophrenic illnesses is towards promoting social improvement rather than cure; on recent

ELECTRICAL CONVULSION THERAPY

CLINICAL OBSERVATIONS

R E HEMPHILL, M D DUBL, D P M
DIRECTOR OF CLINICAL SERVICES AT BRISTOL MENTAL HOSPITAL

SINCE the introduction into this country, more than two years ago, of electrically induced convulsion therapy the method has gained fairly wide acceptance, and enough cases have been treated to allow of discussion of its merits or otherwise, and of the types of disorders for which it is especially applicable

A series of 200 cases (63 in males and 137 in females) of both acute and chronic mental illnesses, in whom treatment has been completed for not less than three months, provides the material for this paper All were inpatients of the Bristol Mental Hospital, but conclusions will be based on additional experience gained in treating others, as well as on the cases in the series

METHOD

The instrument used was a standard machine * in which time can be varied by 0 05 sec and voltage up to 150 volts, the voltage variations are represented by a scale graduated from 0 to 100, and the makers supply a graph on which the real values of these calibrations can be read The general principles and technique have been described elsewhere (Kalinowsky 1939, Fleming et al 1939, Shepley and McGregor 1939, Hemphill and Walter 1941, Androp 1941a) and no important modification suggested itself As a routine, the labyrinth was stimulated by syringing the ear with cold water before inducing the fit This seems to facilitate the return of breathing after the fit

In order to establish a standard and convenient practice, after experimenting with various combinations of voltage and time, in more recent patients the initial time has been set for 0 2 sec, and the voltage increased from the 20th calibration by steps of 20% up to the maximum, if necessary, until a fit results If still ineffective the time alone is increased by 0 05 sec, up to 0 6 sec On the whole, settings of the maximum voltage with durations of not more than 0 3 sec have been adequate for most patients Young males almost invariably have a lower threshold, and in treating these the time is set at first at 0 15 sec In many subjects there is a slight increase in the threshold during the first three or four fits (Kalinowsky et al 1941) which usually remains steady thereafter In a small number of cases the threshold increases after each fit, so that eventually it may be impossible consistently to produce a major convulsion with the maximum voltage and what may be considered the maximum duration of current permissible —namely, 0 6 sec This peculiarity was only observed in women, and it appeared to be a bad prognostic sign It occurred in the rare cases of depression which failed to improve and in one case of hysteria as well as in certain of the schizophrenic group

FRACTURES AND PHYSICAL MISHAPS

The danger of fractures of various bones in shock treatment has attracted attention out of all proportion to its importance, and my experience has not justified experiments with curare and similar drugs recently in vogue (Harris et al 1941) In all patients treated, including many not reviewed here, fractures were noted in 3 compression fractures of the bodies of some dorsal vertebræ in one woman who had sustained an injury of the same sort 14 months before admission to hospital, fracture of the surgical neck of the humerus in a man aged 52, and an extracapsular fracture of the neck of the femur in a physically healthy muscular man of 26 Both fractures of the long bones were noticed as the patient recovered from the fit and could only be explained as the result of violent muscular action Neither the positioning nor the convulsion were in any way unusual in either case Fractures of the humerus have been reported (Gonda 1941, Bingel and Meggendorfer 1940), but to my knowledge no fractured femur has been reported before, although bilateral fracture of the femoral necks has occurred in pharmacological convulsions (Androp 1941b)

Physical illness, sepsis or a prophylactic inoculation within 48 hours of treatment are contra-indications In spite of careful investigation of the physical state, the treatment may have been to some extent responsible for subsequent illness in a small number of cases In 2 apparently healthy patients clinical signs of active pulmonary tuberculosis developed before the third week of treatment, and both died within the next six months, one of miliary tuberculosis with tubercles in most organs including the meninges Autopsy showed evidence of old tubercular foci in the lungs of each, with extensive spread of recent origin It is likely that the violent movements and postconvulsive hyperventilation broke down fibrous barriers thereby activating latent tuberculosis In one young man an extensive tubercular adenitis of the neck developed rapidly after the fourth convulsion In 2 cases recovery from each fit was slow, the pulse being feeble and heart sounds almost imperceptible, and was followed by persistent cardiac arrythmia Although these symptoms disappeared in the course of a week further treatment was deemed inadvisable

DURATION OF TREATMENT

Opinion differs as to how often fits should be induced, or what constitutes a course of treatment Three method have been tried 3 fits weekly, 2 fits weekly, and daily fits for two or more weeks In each case treatment was terminated gradually by 3 or 4 fits each at weekly intervals

The first method seems to be satisfactory for serious psychoses and I find it the method of choice for many such cases In milder illnesses, or where considerable improvement takes place after one fit, it has the disadvantage that the patient seems to become excessively dependent on the treatment and that single day intervals are not long enough to allow a good contact to be made with the outer world—as if the treatment was breaking the continuity of normal life rather than of the psychosis In mild cases of the manic-depressive and psychoneurotic types relapses have been seen when the interval between fits was increased to a week, a disadvantage not encountered so often when only 2 fits per week are tried for two weeks, with increase if there is no improvement Every effort is made to occupy the patient and to get him to take his place in the normal world from the very beginning Relatives are encouraged to visit frequently and take the patient for outings or home for week end He is protected as far as is practicable from contact with other patients who freely express psychotic idea If no improvement has resulted by the 9th fit no further fits are induced, recoverable cases have usually shown improvement before the 5th fit

The daily method was tried in 2 cases of mania and 2 of depression as well as in a number of chronic schizophrenics The manics and depressives relapsed, eventually to recover In both depressives a phase of restless confusion developed and endured for several days After its subsidence psychotic symptoms disappeared The picture in both was rather like postepileptic irritability with confusion and aimlessly violent behaviour There has been a complete and lasting amnesia in both for this phase

In the schizophrenics daily fits were induced for upwards of 30 days No beneficial effect was observed at the time, some being more confused and uncooperative, but in subsequent weeks several patients showed more sociable conduct, became clearer and could be employed They have not relapsed In some there was a loss of weight and physical deterioration after the first week This was attributed to inadequate nourishment, these chronic patients came from large refractory wards where they could not possibly receive individual supervision at meal times After induced fits they were sometimes confused and disinclined for the midday meal As breakfast is normally withheld on the morning of treatment, these patients often took little nourishment

be equal to 6 cm of water Thus a column of fluid (of approximately the same specific gravity as water) connected to the vein and 6 cm in height would be in equilibrium with the blood in the vein If this column of fluid is lengthened to some 50 cm and ends in a closed drip chamber it is obvious that there is a negative pressure of 44 cm of water in the drip chamber Now if fluid is allowed to enter the drip chamber at a slow rate, it will also enter the vein at the same rate but the negative pressure in the drip chamber will not be materially altered, since the maximum flow through the needle that is possible is much in excess of the amount entering the drip chamber With the advent of a leak in the rubber tubing (and owing to the rubber shortage the risk of this increases daily) air is sucked into the tube Fluid, however, is still flowing down the tube, and its surface tension holds it as a short column filling the lumen Thus a column of air and fluid alternating will pass down the tube and through the needle

A METHOD OF PREVENTION

The screw clamp, instead of being on the rubber tubing between the blood bottle and the drip chamber, should be clamped on the tubing only 2 or 3 cm above the needle in the vein In this position the rate of flow is as easily controlled as before, but in addition it will be found that there is now a positive pressure in the apparatus above the clamp and any leak occurring will allow fluid out and not air in

LIVER ABSCESS FOLLOWING PERFORATED DUODENAL ULCER

K W G HEATHFIELD, M B LOND
LATELY RESIDENT MEDICAL OFFICER AT THE ROYAL HOSPITAL, WOLVERHAMPTON

SOLITARY liver abscess as a sequel to a perforated duodenal ulcer is sufficiently rare to be worth recording The following case presented great difficulty in diagnosis, the clinical picture being that of non-hæmolytic streptococcal septicæmia

A man of 25 was first admitted to the Royal Hospital, Wolverhampton, on July 8, 1941, with a month's history of gastric dyspepsia, culminating in a sudden access of pain in the epigastrium on the day of admission There was board-like abdominal rigidity with great tenderness, and the diagnosis of perforated duodenal ulcer was confirmed at operation, when the perforation was closed under general anæsthesia After the operation he had a daily spike of temperature, ranging between 99° F and 100° F for the first week, which was attributed to a postoperative bronchitis He was discharged to a convalescent home on July 27, and to his own home on Aug 9 He was readmitted on Sept 30 with a story of gnawing abdominal pain round the umbilicus, made worse by deep respiration, he was feverish, and had had shivering attacks for the past two weeks He was very pale and toxic looking with considerable mental hebetude, tongue furred, severe pyorrhœa, heart sounds very distant, slight tenderness in the right side of the abdomen, otherwise physical examination was negative A provisional diagnosis of subphrenic abscess was not confirmed by radiograms of the abdomen, and the patient was too ill to be screened Blood count red cells 3,200,000, Hb 63%, white cells 12,300 (polymorphs 81%, lymphocytes 13%) Urine a fair amount of albumin scanty red cells, cultures grew no non lactose fermenting organisms, films of fæces showed pus and a little blood, cultures again grew no non lactose-fermenting organisms Widal test positive to typhoid H 1 in 500, paratyphoid A 1 in 25, paratyphoid B 1 in 50, negative to typhoid O he had, however, had injections of TAB during the last war Blood culture yielded a profuse growth of non hæmolytic streptococci

He ran an intermittent temperature, which rose to 102° F in the second week when he began to have almost daily rigors A course of sulphapyridine (2 g followed by 1 g 4-hourly for a week) was given, which brought down the temperature, but when the drug was discontinued it immediately rose to 101° F On Oct 17 his condition had greatly deteriorated, pulse had a very poor volume, blood-pressure 70/50 mm Hg, heart sounds very faint, no bruits audible Spleen was palpably enlarged, though soft, three finger-breadths below the costal margin On Oct 22, blood-count 20,000 white cells (polymorphs 84%) Blood-culture again yielded non-hæmolytic streptococci The agglutination to typhoid H had now risen to 1 in 1250 He continued to complain of intermittent acute pains in the right iliac fossa, while the temperature rose to 102° F each evening, he looked jaundiced at times, becoming progressively anæmic (on Oct 29 Hb 38%, red cells 1,880,000) and towards the end drowsy On Oct 31 he was given 2 pints of blood and sulphathiazole was begun In spite of these measures, however, he died on Nov 4

At autopsy, the liver was enlarged, but the external surface showed no abnormality The right lobe contained a large abscess about 3 in in diameter, cultures from this grew gram-positive cocci in chains The spleen was enlarged and septic Granular and contracted kidneys indicated a severe chronic nephritis

I can find only 2 cases of this kind reported in the past 20 years and both were abroad [1] The septicæmic state, wth enlargement of the spleen, subclinical jaundice, leucocytosis, drowsiness, and intermittent pyrexia with rigors are typical of the liver-abscess syndrome whatever the organism

I should like to thank Dr J H Sheldon for permission to publish this case

Medical Societies

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE

AT the meeting on July 23, a discussion on the

Treatment of Malaria

was opened by Sir RICKARD CHRISTOPHERS FRS Symptomatic treatment intended to relieve the vomiting nausea high temperature and other distressing symptoms associated with malaria, is he said important, but we should not get far if, as physicians had once to do, we had to rely on such treatment alone Nowadays our sheet anchor is the specific drug Up to the last 10 years or so the only specific drug of any distinct potency was quinine Cinchona no longer comes mainly, if at all from the forests of Peru but unfortunately its cultivation especially that of the heavily quinine-bearing forms, has become more and more concentrated in Java, until for a long time that country has held a monopoly With Java now closed to the allies we must look forward to the supply being seriously curtailed, and the production of substitutes must become a most urgent matter Quinine is not the only alkaloid obtainable from cinchona, especially in the more robust and low-grade quinine-yielding species commonly grown in India it may form less than 10% of the total alkaloids Cinchona contains four crystallisable alkaloids—quinine, quinidine, cinchonine and cinchonidine, as well as amorphous alkaloidal material termed quinoidine Cinchonine and quinidine are about equally effective with quinine, while cinchonidine is also somewhat active These other alkaloids occur in amounts collectively considerably greater than does quinine itself, and they have been in use, especially in India, extracted from the bark along with the quinine as cinchona febrifuge, or after the quinine has been removed as quinetum Cinchona febrifuge contains about 7% quinine and 47% of other crystallisable alkaloids A product of this type, totaquina guaranteed to a standard content of not less than 70% crystallisable alkaloids, of which not less than a fifth must be quinine was recommended by the League of Nations on the view that it would make an effective antimalarial remedy available to a greater proportion of the population

Besides these naturally occurring alkaloids there are various derivatives of the quinine type, notably hydroquinine, considered by some authorities to be even more effective than quinine and to be free from some of its undesirable effects However, it is doubtful whether total alkaloids or any quinine derivatives could meet the demand for efficient substitutes, for this purpose we must turn to recently developed synthetic antimalarials About 1924–26 Schulemann, Schonhofer, and Wingler, working in conjunction with Roehl, synthesised 'Plasmochin,' and this brilliant feat in chemotherapy enormously stimulated research In 1932 Mietzsch and cases its effect may be much more favourable No doubt, as others have found, really early treatment brings about a fair percentage of recovery

There were no immediate fatalities in more than 200 cases of mental disorders treated by electrical convulsion therapy, but unrecognised latent tuberculosis may have been reactivated in 3 Three fractures were seen of the humerus, the neck of the femur and of the dorsal vertebræ The only schizophrenics that recovered had been ill for less than a year Spontaneous remissions were observed in 2 schizophrenics after unsuccessful shock treatment, and prefrontal leucotomy was responsible for improvement in 3 other shock treatment failures

MEASURING CEREBROSPINAL FLUID PRESSURE

P W Nathan
M B LOND, M R C P
CAPTAIN R A M C

C W M Whitty
B M OXFD
CAPTAIN R A M C

(*The Military Hospital for Head Injuries*)

The Dattner lumbar-puncture has been used mainly in venereal diseases clinics It has not been adopted by neurologists and physicians because the measurement of the spinal-fluid pressure is said to take fifteen minutes (Erskine and Johnson 1938)

The needle is based on the trocar and cannula principle, but the cannula is itself a fine (size 18) needle with a stylet within it This fine needle of shaft length 10 5 cm fits within a wider bore needle of shaft length 7 cm A screw on the outer needle can be tightened to hold the inner one in place In use the inner needle is arranged so that its point is level with that of the outer and the screw tightened The whole needle is then introduced as far as the dura The screw is loosened the fine needle pushed into the theca and the screw tightened The hole made in the dura is small This prevents leakage of CSF, the probable cause of lumbar-puncture headaches (Ingvar 1923, Nelson 1930) This would agree with the findings of many VD clinics both here and on the continent that punctures can be done by this method on outpatients with fewer subsequent headaches than when Greenfield's, Pitkin's or Harris's needles are used on patients kept in bed for 24 hours afterwards (Erskine and Johnson 1938) To measure the pressure we have adopted the following procedure

A clip is placed on the rubber tubing connecting the manometer to the needle Sterile saline is introduced by means of a syringe and needle into the manometer bulb The clip is loosened and saline allowed to run out until there is a column of fluid in the manometer equal to the expected CSF pressure, we usually select the 100 mm mark The puncture is then made When the fine needle is within the theca fluid is aspirated just to the end of the needle The manometer is then connected and the clip loosened A continuous fluid system is thus formed from within the dura to the manometer It is necessary to wait 1–2 minutes for the manometer level to become stationary Queckenstedt's test can then be performed Pressure should be applied first to the uppermost side (the side on which the patient is not lying), for when there is no block this gives a smaller rise than the under side Thus a wait for the first reading to return to its resting value is avoided, since we may expect pressure on the second side to give a reading above that on the first The rise is slower than with a wider needle, but with unilateral pressure a rise of 15–30 mm in half a minute has been found to indicate no block Bilateral pressure afterwards can give a further 20–30 mm rise A fall of 10–20 mm will occur within one minute of releasing the pressure

In a series of diagnostic punctures on hospital inpatients we have confirmed the pressure reading, by removing the inner needle, pushing the outer needle through the theca and re-taking the pressure in the usual way The reading has always corresponded within 5 mm

When the fluid is greatly thickened with cells this method is not applicable But we have used it successfully with protein values of 400 mg per 100 c cm, and with fluid which looked like pure blood If the fluid is too thick the outer needle can be introduced into the theca without making another puncture

The technique is no more difficult than with ordinary single needles One rapidly learns the feel of the outer needle piercing the ligaments, and the slight resilient "ping" as the inner needle enters the dura

Besides the advantage of being able to make a full CSF examination on an ambulant patient with less fear of complications, we believe that in cases where pressure is thought or known to be high this is the method of election Pressure can be read with the removal of only 0 5 c cm of fluid, and the risk of subsequent leakage through the dural tear is reduced The chief limitation to the routine use of the Dattner needle—that the pressure cannot be satisfactorily recorded—thus seems to be removed

We are grateful to Lieut Colonel G O Chambers, commanding officer of this hospital, for permission to publish this note

AIR ENTRY THROUGH TRANSFUSION SETS

M B Devas, B A CAMB
STUDENT AT THE LONDON HOSPITAL

Recently several deaths from air embolism following transfusion have been recorded I would like to point out the ease, under certain conditions, with which large quantities of air can be pumped into a vein through a transfusion apparatus working solely by gravity I performed the following experiments

An ordinary blood transfusion apparatus was set up with a bottle of plasma instead of blood, so that visual observation might be more accurate The apparatus consisted of the inverted plasma bottle, fitted with a rubber cork through which ran an inlet and an outlet tube The outlet tube was connected by rubber tubing to a Laurie type of drip chamber, of which the side arm was attached to a short length of rubber tubing closed with a spring clip From the drip chamber ran another length of rubber tubing to a metal connecting piece fixed to a standard intravenous needle The needle was placed in a trough of water 6 cm deep wit a calibrated measuring cylinder inverted over it to measu the quantity of air that might emerge The flow of plasm was controlled by means of a screw clamp on the rubb tubing above the drip chamber

Expt 1 —The flow through the drip chamber was adjuste to 2 5 drops per sec and was left running for a few minute A fluid level was present in the drip chamber and no air cam through the needle Then the spring clip on the side tul was removed and, contrary to the usual teaching that tl fluid in the chamber would rise and overflow through the sic tube, the level immediately vanished and in a few momen air was coming through the needle at the rate of 23 c cn per min

Expt 2 —The flow through the drip chamber was adjuste to 0 67 drop per sec, with the spring clip closing the sic arm A leak in the rubber tubing was then simulated b plunging a no 12 hypodermic needle into its lumen, 5 cn below the fluid level in the drip chamber Immediately a could be heard entering the tube, and in a few moments we being collected from the intravenous needle at the rate 1 6 c cm per min Throughout the fluid level in the dri chamber remained constant The rate of flow was the increased to 1 3 drops per sec, and air was collected a 5 2 c cm per min A further increase in the rate of flow t 2 8 drops per sec resulted in air being collected at the rat of 10 3 c cm per min No change was noticed in the flui level in the chamber

The venous pressure in the arm of a recumbent patien varies greatly with the exact position of the arm and th general condition of the patient I have assumed it t

Although the infections were usually controlled while the patients were taking these long courses, many relapsed within a few weeks of the end of treatment The general conclusion was that as a suppressive treatment interrupted is preferable to continuous quinine treatment in simple tertian malaria

On these observations the method of treatment which has been successfully followed in Liverpool for many years has been devised It consists in controlling the acute attack by giving gr 30 of quinine sulphate in solution daily by mouth for four consecutive days, the patient is then discharged and told to take gr 20 every Saturday and Sunday for the next eight weeks, and if he relapses after that to continue the week-end treatment for a further period The dosage is very possibly on the liberal side, but before the present shortage that did not matter Now it is necessary to take every step possible to reduce consumption Regarding the imperative necessity of controlling the acute attack, especially in an unacclimatised population, there can be no doubt, but the amount of quinine used for prophylactic or suppressive purposes is probably much greater than that used for acute attacks, and much of that is wasted It might well be argued that better results would be obtained from simply treating acute attacks Suppressive treatment is obviously necessary for troops campaigning in malarious countries and for seamen voyaging to malarious ports, but treatment of the acute attack is essential, and if there is any shortage of antimalarials it is the suppressive form of treatment which must be drastically reduced We must also not waste the drug in the treatment of acute attacks Thus the total dosage in a course suggested by the Army medical authorities is gr 400, if this is designed simply to treat the acute attack probably at least three-quarters of the quinine is wasted, and if it is intended to sterilise the infection it will fail, much quinine could be saved if it were abandoned Professor Yorke expressed surprise at Sir Rickard Christophers's denunciation of the intramuscular use of quinine He agreed that the repeated administration of intramuscular injections in chronic malaria is simply a money-making device, but did not agree that the method is unjustified in serious cases with pernicious manifestations because the necessary rapid absorption could not be expected He has found one or two intramuscular injections of quinine bihydrochloride invaluable in the treatment of really serious cases where the patient must absorb some of the drug quickly Considerable quantities of injected quinine can be found in the muscles of experimental animals weeks after the injection, but sufficient is absorbed to produce the desired results In Liverpool many hundreds of intramuscular injections have been given during the last 25 years, they have produced none of the suggested ill effects and have saved many lives

Finally Professor Yorke referred to the so-called standard Army treatment of malaria, which runs as follows days 1–2, quinine gr 30 daily, days 3–7, mepacrine 0 3 g daily, days 8–9, no treatment, days 10–14 pamaquin 0 03 g daily. This bears no resemblance to Sinton's combined pamaquin-quinine treatment, and he asked whether there is any evidence that pamaquin given in this way does reduce the relapse-rate in either simple tertian or malignant tertian malaria, and if not what it does that the quinine or mepacrine alone would fail to do

MALARIA IN A HYPERENDEMIC ZONE

Dr WILLIAM HUGHES, of the Nigerian Medical Service, explained why the treatment of malaria in a hyperendemic zone presents problems which do not arise elsewhere In endemic malaria the parasite is most often *Plasmodium vivax*, in hyperendemic malaria it is usually *P falciparum* In endemic malaria severe and fatal cases occur at all ages, in hyperendemic malaria nearly all the severe cases and all the mortality occur in childhood In endemic zones the incidence and severity of the disease will be the same in the native population as among newcomers, in the hyperendemic zone while the native population flourishes the newcomers are rapidly killed off unless protected against infection or treated for the disease In the endemic zone infection is comparatively scarce and immunity practically non-existent, in the hyperendemic zone infection is universal and intense during youth but declines towards old age as immunity is established Hence an epidemic may arise in an endemic zone or among non-immunes when for any reason infection becomes more widespread and intense, whereas an epidemic cannot occur in the native population of a hyperendemic zone On the whole, then, the native population in a hyperendemic area are well off compared with those in places where malaria is only endemic Attempts at prevention of infection in a hyperendemic area by antilarval measures may do more harm than good, and even in the treatment of bouts of fever associated with infection we should try to interfere as little as possible with the development of immunity

In such an area quinine should not be given in the vast majority of cases of malaria in adults, because natural recovery will take place without, it will probably interfere with the development of immunity, if quinine becomes scarce it should be reserved for the severe cases seen in children and immigrants, and finally because it confuses the diagnosis, so that, for example, a case of tuberculosis is treated as malaria in the early stages when it is most amenable to the correct treatment According to Barber 48 6% of adults in Southern Nigeria show parasites in their blood, so that the usual diagnostic criteria—parasites and fever—do not hold in the hyperendemic zone The indications for treatment in native children are difficult to define They are in the process of gaining immunity—between the ages of 1 and 4 years the parasite rate is over 90%—and to treat infection per se will check this process There are, of course, cases where urgent treatment is required Fortunately the total amount of quinine needed to cure the fever is very small Most cases require injections of quinine, and gr 5 can be given intramuscularly with safety at any age The potential severity of the disease finds an adequate medium of expression in adult Europeans Immunity could never be allowed to develop in them on account of the virulent course the disease takes in uninfected adults Prevention of infection by antilarval measures is not practicable The habit of taking gr 5 or so of quinine daily has stood the test of time, but has many drawbacks The dose for each individual has to be adjusted, often by trial and error It does not prevent infection and is inadequate once fever occurs It so reduces the parasite content of the blood that it often confuses diagnosis, and is the indirect cause of low fever and so-called tropical neurasthenia Possibly some cases of mental deterioration and alcoholism could be traced to it too

The standard treatment for an attack of malaria in a European in Nigeria was gr 20 a day while the fever lasted, gr 15 daily for the next few days, gr 10 daily for perhaps another week and then back to the routine gr 5 There has recently been a reversion to heroic dosage For the acute fever gr 30 of quinine is given daily by mouth plus gr 10 intravenously, together with 0 4 g of mepacrine The maintenance dose is gr 15 of quinine and 0 1 g of mepacrine daily This heroic regime is unnecessary in most cases There may be something to be said for the large maintenance dose in certain emergencies—for example, a civilian on a long trek or a soldier actually in the battle zone Dr Hughes prefers the usual textbook regime of gr 30 daily for the acute stage and a maintenance dose of about gr 5 Injections of quinine are often required Fatal accidents have occurred with intravenous injections, due to giving quinine too rapidly in a concentrated solution Intramuscular injection is safe and painless if the syringe is boiled immediately before use and the injection is given very slowly—2 minutes is not too long to take Fever should be treated promptly The advice to allow the fever to subside before giving quinine has led to fatalities on board ship If quinine is not given quickly incessant vomiting and coma may develop Headache is a common symptom when there is high fever and some residual headache may remain for anything up to three months in cerebral cases It should be prevented by prompt treatment with quinine and aspirin The patient can be instructed to take up to gr 60 of aspirin a day if necessary Purgatives are not necessary in the acute stage, and they cause abdominal distension by hurrying on the undigested food to ferment in the large bowel

Mauss, working with Kikuth, synthesised 'Atebrin,' probably the most powerful antimalarial at present known A number of compounds of these two types were synthesised by Fourneau and are known as Fourneau compounds Since then many more or less closely related compounds have been made in different countries The main ones are mepacrine (*BP*), 'Quinacrine' and 'Acriquine' which are probably identical with atebrin, pamaquin, 'Praequine,' Fourneau 710, 'Rhodoquine' and 'Plasmocide,' which are identical with plasmochin or 'Plasmoquine' Fourneau 915 or 'Rhodoquine V', and 'Certuna' and Cilional which have an effect similar to that of plasmochin with much less toxicity

For practical purposes we have two well-established forms of compound in general use as synthetic antimalarials—viz (to give them their English official names) mepacrine and pamaquin Pamaquin has the remarkable property of acting on the sexual forms of the parasite Attempts to control malaria in communities through this action have however, not met with much success, though it may have a use in reducing the chances of the spread of infection from cases in hospital It is more and more employed as a sort of adjuvant to quinine or mepacrine especially in after-treatment and so-called prophylaxis but is now rarely used in treating the acute disease because it is rather toxic and not very effective against the asexual stages of the falciparum parasite It is considered by many authorities to have a beneficial effect in reducing the liability to relapses especially when used in after-treatment or prophylaxis along with the more effective schizontocidal drugs quinine or mepacrine For this purpose it is given in very small doses, usually not exceeding 0 02 gramme, and then for short periods or well spaced It is also put up in combination with quinine in tablets It is not thought desirable to administer it at the same time as mepacrine Pamaquin cannot be considered as a satisfactory substitute for quinine in treatment of the acute disease or by itself in after-treatment or prophylaxis, but mepacrine is generally accepted as at least as effective as quinine in the acute disease in reducing liability to relapse and in so-called prophylaxis

Since all our ideas regarding treatment have been largely built up on quinine, Sir Rickard Christophers recapitulated what has been learnt about the use of this drug We are not now so insistent on timing our dosage to catch the sporulation forms, but try to ensure that there will always be a sufficiency of quinine in the blood through the period of treatment Largely as a result of the splendid researches of Stephens and his collaborators at Liverpool during the last war we now know that the heroic doses once given are useless We do not now give more than gr 30 in a day—three doses of gr 10—and many consider gr 20 a day adequate in acute malaria Again we know, largely from the Liverpool experiments, that it is no use trying to eradicate infection by unduly long administration, most authorities now prefer to space administration suitably, usually with an interval or change of treatment About 7 days' treatment is commonly considered suitable to cover the period of the attack For so-called prophylactic use there are the two common methods of gr 5 (or 7) daily or gr 15 on two successive days in the week, gr 7 daily is probably the best dosage, gr 10 daily is not suitable for long periods A good deal has to be allowed for fatigue, sun, cold, &c to which the treated person is exposed In the main these results are applicable to mepacrine With this drug we give not more than 0 3 gramme in the day in three doses of 0 1 g The toxicity is not apparently great There is a liability to some gastro-intestinal effects or abdominal pain, and, especially in native races, nervous or mental symptoms Mepacrine has a definite cumulative effect so that the total daily dosage is pretty well fixed, and the periods for which it is administered must be carefully watched Usually in the acute attack it is given for not more than 7 days, and if necessary repeated again after an interval In prophylaxis the dosage must be cautious—say 0 2 g on two successive days in the week or even at longer intervals Mepacrine is a powerful yellow dye and liable to give rise to yellow coloration of the skin, but this is in no way harmful, it is said that the sclerotics are not affected It is supposed that mepacrine does not, like quinine, precipitate blackwater, but cases following mepacrine have been described It is also said to be less liable to bring ab abortion than quinine, but this is uncertain Ther one feature in which mepacrine has a clear advant over quinine—in its suitability for intramusc injection

Treatment in the ordinary case of malaria is l carried out by oral administration, but if there cerebral or other pernicious manifestations parent administration is not only a matter of necessity bu urgency With quinine this must be by careful in venous injection, either using a dilute solution or injec the drug very slowly Intramuscular use of qui in such circumstances is unjustified as the necessary r absorption could not be expected Intramusc injection of quinine is not so much used in pernic malaria as in chronic cases thought to be resistant use of intramuscular quinine for such a purpose is lar the perquisite of the doctor babu or low-class practitio In the opinion of many it amounts to malprac Probably the case is not malaria to start with results at best form a necrotic mass in the tissues an the worst lead to tetanus or serious sloughing In muscular injection of mepacrine, on the other hand accepted as a correct procedure, and it does not ca sloughing Mepacrine methanosulphonate *BP* ('Ate Musonate,' 'Quinacrine Soluble'), a more soluble sal the alkaloid, is put up in ampoules for injection mepacrine then we have a good substitute, and at pre the only one, for quinine That this is the last wor synthetic antimalarials is improbable Thus cer arsenical compounds have been shown by Yorke to h a remarkable sterilising effect on certain forms of mala Sulphonamides have not so far given much indicatio their usefulness Glyn-Hughes, Laurie and Yorke h in testing out compounds of the synthalin type fo that at least one of these, undecane-1 11-diamidine effective against malaria—an entirely new type antimalarial compound

LESSONS FROM THE LIVERPOOL SCHOOL

Prof **Warrington Yorke** said that two facts se of overriding importance—that we have lost Java with it over 90% of the world's supply of quinine, that our troops are already operating in many malari countries and many of our ships are calling at malari ports It seems obvious, therefore, that the demand antimalarial drugs will increase enormously T serious situation demands immediate action in manufacture of an adequate quantity of the only effic synthetic substitute for quinine, namely, mepacr and in the conservation of existing stocks of quin The only way in which we can materially cons quinine is by using it as economically and efficientl possible in the treatment of malaria It is a remark fact that there is no unanimity of opinion on how it best be used The extremely low toxicity of quinine encouraged the use of unnecessarily large doses In researches at the Liverpool school in the last war, attempt was made to decide on the smallest amoun quinine necessary to control the acute attack Pati suffering from acute simple tertian malaria were trea with quinine in doses ranging from gr 5 to gr 12 each of two consecutive days only Even in the gr treated with gr 5 parasites disappeared from the p pheral blood and the temperature became norma over 80% of cases, and this always happened when doses were gr 10 or more Within a few weeks, howe most cases in all the groups had relapsed—even th given gr 90–120, which is beyond the limit of tolera for most people These results suggested that in treatment of acute simple tertian malaria nothing to be gained by giving more than gr 20 or gr 30 couple of days, and that it was impossible to produ sterilisans magna by pushing the dosage to a de which was definitely toxic A series of cases of a malignant tertian malaria were given a similar two treatment of gr 30 of quinine and here again the t perature became normal and trophozoites disappe from the blood in all of them With the object of fin whether a definite cure can be obtained by a long co of large doses of quinine, cases of simple tertian mal were given daily doses of up to gr 45 by mouth for as l as eight weeks, and others were given the same do on two consecutive days only for the same per

THE LANCET

LONDON SATURDAY, AUGUST 8, 1942

DIPHTHERIA IN THE IMMUNISED

In analysing the incidence of diphtheria among the inoculated in Liverpool since 1925, Glover and Wright[1] have drawn attention to an odd gap in reported results of immunisation Many figures for the response to the Schick test or the antitoxin content of the blood after immunisation have been published, but there have been few records of what really matters—the subsequent history of such children as regards diphtheria infection In Liverpool no Schick tests or antitoxin estimations were done, this was a plain clinical tale, though it points more than one moral From October, 1925, to the end of 1938, 54,985 persons had been inoculated with five varieties of prophylactic, one of them (MT) now long obsolete Among this total 396 had, up to the end of 1939, contracted diphtheria and 11 of them had died, all the fatal cases were in children under school-leaving age and 6 of them had been inoculated with the admittedly unsatisfactory MT In every case, fatal or not, the virulence of the infecting strain was established, with few exceptions these were gravis or intermedius strains, all the fatal cases being caused by one or other There is clear evidence too of the greater preponderance of these more virulent strains among inoculated patients than in diphtheria cases in the city as a whole Yet cases in the inoculated were mostly very mild Even so, Glover and Wright consider that they were too numerous In part their number is ascribed to the weak prophylactic (MT) used in the early days No Schick tests were done after immunisation, so it is not possible to say whether the infected child was a Schick immune, some children of course are refractory to immunisation

So much for the debit side of the account, to the credit of immunisation there is the outstanding fact that whereas between 1933 and 1939 the case-rate among uninoculated children under the age of 10 years averaged 11 3 per 1000 per annum, among inoculated children it ranged from 1 5 to 3 0 The observation that in Liverpool the diphtheria rate over the age of 10 is much the same in the uninoculated and inoculated deserves further epidemiological study Much remains to be done Liverpool is heavily infected with highly virulent strains of the diphtheria bacillus and is inhabited by a population coldly indifferent to the offer of free immunisation Up to the end of 1939 only 6% of the preschool children and only 31% of those between 5 and 9 years had been inoculated Since at least 30% of preschool children must be immunised to affect incidence it can be no surprise that there has been no decline Liverpool has always been in the forefront of advances in public health and it is unlikely that this state of affairs will continue indefinitely provided personal approach to parents can be contrived and local practitioners cooperate fully

Meanwhile, figures such as those of Glover and Wright far from lessening confidence in immunisation should enhance it The prophylactic used, in Liverpool as elsewhere, is all-important, and it is satisfactory to know the care that is now taken by the Ministry of Health, as the licensing authority, to ensure that APT issued to local authorities for the use of practitioners is of high antigenic potency[2] It is important, too, as Bousfield[3] points out, that statistics published from various sources should be comparable If this is to be achieved, technique and the collection and presentation of data must be uniform, Bousfield sets out more than twenty possible sources of error which may account for the widely divergent results of immunisation campaigns

SYME'S AMPUTATION

Almost exactly 100 years ago[4] a boy of 16 was admitted under James Syme in Edinburgh for multiple sinuses of the foot involving the tarsal bones Amputation was essential but since both calcaneus and astragalus were involved Chopart's amputation, devised 50 years previously, was impossible and an amputation below the knee was the only alternative Syme[5] decided to amputate through the ankle-joint and thereupon fashioned a flap from the heel, dissected out the calcaneus, and with some straight bone-cutting pliers which had lately been designed by Liston removed both malleoli to leave an end-bearing tibial stump Although some sepsis followed and there was partial sloughing of both upper and lower flaps he records a satisfactory result A few months later a "medical gentleman" aged 25 was sent to him suffering from caries of the ankle-joint, where Syme[6] added to his operation by sawing off a slice of the tibial mortice The adherent skin due to disease may have been partly responsible, yet the novice will be comforted to know that Syme buttonholed his flap in dissecting out the calcaneus However, he records that this opening gave efficient drainage

For over three-quarters of a century Syme's was regarded as the most satisfactory of all lower-limb amputations, though there were some modifications The classical skin flap was found to be too bulky and an elliptical type of skin incision came to be employed, taking just over a finger's breadth of the heel sole, and the tibia was sawn through half an inch proximal to the articular surface Elmslie in this country is usually said to have devised this, the French[7] call it Guyon's method, but he also retained a slice of calcaneus in the heel flap After the last war the Ministry of Pensions surgeons at Roehampton had special opportunities for observing the results of different amputations, and they came to the conclusion that end-bearing stumps were unsatisfactory Three-quarters of 12,000 cases where the stump was end-bearing had to have re-amputations, 38 out of 54 Syme cases had to be re-amputated In 1927 the end-bearing stump operation became obsolete in the ministry's hospitals and they decided that even the Syme had to go It was their experience that the Syme stump soon developed callosities and that the operation was difficult to do well, so that when the flap settled it was often displaced backwards or to one side Any attempt at refashioning the flaps invariably failed But their greatest objection to the

When a European leaves the hyperendemic zone the general rule has been to recommend gr 5 of quinine daily for 2 months, but there have been many failures and some cases of blackwater fever with this regime Dr Hughes now recommends a course of mepacrine and quinine beginning ten days after leaving the coast The course consists of 0 2 g of mepacrine and two gr 5 tablets of quinine daily for seven days The results in fifteen cases have been successful Whether strangers who visit the coast should take quinine depends on the length of stay, the localities they visit and the season of the year If the probabilities are in favour of infection Dr Hughes advises prophylactic quinine and after-treatment In the treatment of blackwater fever alkali therapy is a sine qua non whether blood is transfused or not The urine should be rendered alkaline within twenty-four hours Low fever requires careful diagnosis There are genuine cases which run a temperature of 99°–100° F for weeks at a time The most frequent causes are malaria and pyelitis If quinine is discontinued for 4 or 5 days repeated examination of the blood will usually settle the diagnosis A bout of fever with rigors in such cases is not a bad thing The minimum period of convalescence after an attack of malaria should be a week from the last rise in temperature As regards troops in a hyperendemic zone, Wenyon in his survey of malaria in Macedonia during the last war emphasised the impossibility of preventing malaria by antilarval measures in the fighting zone, and the last war was mainly static while this one is mobile Antilarval measures are therefore out of the question now It might be urged that under camp conditions troops could be protected from infection, but actually such protection is almost impossible to achieve In the remote event of it being successful it might promote a feeling of false security

SOME CLINICAL EXPERIENCE

Sir Philip Manson-Bahr said he had never departed in the main from the opinions he based on his initial investigations into the synthetic antimalarial drugs He had been the first in this country to investigate the potentialities of plasmoquine and plasmoquine compound in 1926 and 1927, and later had done similar work on atebrin There could be no doubt that by their aid the therapeutics of malaria had been greatly improved At present the rôle of pamaquin was as an adjunct to quinine in the treatment of benign tertian malaria, and especially in the prevention of relapses which constituted such a feature of this infection in the prolonged quinine anti-relapse treatment of former days It was now fairly certain that relapses could be prevented by courses of moderate quinine and pamaquin dosage Mepacrine, on the other hand, was of little service in suppressing this infection, but was specific for the subtertian form, especially in combination with quinine in small doses (gr 10 daily) He had advocated this method in the past ten years and had seen no reason to regret it, but he was not impressed with the benefits of parenteral injections of mepacrine (atebrin musonate) Occasionally intramuscular abscesses formed and might be large As regards intravenous injection he had reason to believe that in cerebral malaria its action was too slow to be effective and he had seen cases so treated which showed no signs of improvement till intravenous quinine (gr 10 of the dihydrochloride) had been substituted In a recent case there appeared to be no reduction in the number of circulating parasites, or alteration of their morphology, after two intravenous injections of atebrin musonate He had been impressed with the prophylactic value of mepacrine in preventing the development of subtertian malaria, and he had for years advised a five-day course of mepacrine to be taken by officials and others during the homeward voyage from West Africa He had always regarded intramuscular quinine as a most valuable therapeutic measure in severe subtertian malaria He had never had serious mishap and he was convinced that the evil reputation this method had sometimes acquired was due to the practice of giving repeated injections into the same area, whereas two or at the most three injections were ample under any circumstances

Reviews of Books

Stitt's Tropical Diseases

(6th ed) Richard P Strong, M D Sc D London H K Lewis 2 vols Pp 1747 £5 5s

It is now thirteen years since the fifth edition of this book appeared, the sixth edition has been rewritten and has swelled to two volumes Dr Strong's aims have been to summarise our knowledge of the clinical manifestations and treatment of tropical diseases and of important zoological aspects and laboratory measures relating to diagnosis, prevention and transmission As a result the book now takes its place as an authoritative work on tropical diseases The arrangement is on an ætiological basis, he deals in turn with the protozoal, the bacterial and the virus diseases, the disorders of nutrition, diseases which cannot be satisfactorily classified, and the fungous and helminthic diseases He admits that he has only considered briefly the more important cosmopolitan diseases encountered in warm countries, and in any case a book on tropical diseases in the strict sense would consist of two chapters—one on tokelau and the other on pinta However, to give 12 pages to trench fever (which is neither an important cosmopolitan disease nor particularly incident to the tropics) and only one page to smallpox, admitted to be "the greatest scourge of the natives of tropical countries," is disproportionate, and to devote two pages to a detailed account of the magnesium sulphate treatment of tetanus while dismissing the use of bromethal in half a line is to emphasise a method which should now be allowed to die a natural death

The first two sections dealing with the protozoal and bacterial infections are the best in the book, and the chapters on malaria and blackwater fever are full and could hardly be bettered Ascension and St Helena should be added to the list of tropical islands which are free from malaria, and the use of people who have lived in malarial countries as blood donors should be called impermissible, not merely dangerous Sternal puncture—a method of investigation which should entirely replace splenic and hepatic puncture—is rightly advocated in malaria and in the leishmaniases More might have been said of the work of the last ten years on sylvatic or jungle yellow fever, and on the recent work on typhus in Malaya The chapter on sprue is somewhat inadequate but the other recognised disorders of nutrition are well described The criteria used nowadays in making a diagnosis of beriberi are not discussed—unfortunately, since the estimation of blood pyruvic acid is unquestionably of value Particular attention has been paid to the zoological aspects of the helminthic diseases Pinta, now known to be caused by a treponema, is classified today among the bacterial instead of the fungous diseases The probable connexion between clonorchiasis and primary carcinoma of the liver, and the use of the gold salts in the treatment of clonorchiasis both deserve some mention The excellent appendix on tropical hygiene gives advice on everything from mosquito-boots to the "disinsectisation" of aircraft The objectivity and freedom from bias are very pleasing throughout for example, the remark "it is well to remember that not all degenerative diseases of the nervous system are due to deficiency of vitamin B_1"

Aids to Osteology

(4th ed) Nils L Eckhoff, M S Lond, F R C S London Bailliere, Tindall and Cox Pp 260 6s

This book made its first appearance some twenty years ago The last edition, like many other books, suffered from enemy action, but the opportunity thus made was used to review the text and introduce more figures As a result Mr Eckhoff has written a fourth edition of high level—clear, accurate in detail, and illustrated with figures likely to be of service to the reader who has not the bones themselves under his eyes Unfortunately the illustrations are only in the sections dealing with the trunk and limbs, simple line drawings would make the Chinese puzzle of the skull bones much more comprehensible holding 1 part of hæmoglobin per million parts of water We are said, nowadays, to require 60 mg of ascorbic acid every day for optimum health This is 10–20 times less than our calcium requirement and is only 20 parts per million of our total intake of food and water Looked at in another way, however, this is really quite a large amount and it could be weighed with accuracy on any good chemical balance We require only a fifth of this weight of iron or zinc and much less copper per day An adult s requirement of vitamin D is said to be 100 to 200 international units per day This sounds a lot, but 1 gramme of calciferol contains 40,000 000 IU of vitamin D, so that by weight our daily requirement is only $\frac{1}{200}$ to $\frac{1}{400}$ of a milligramme Our iodine requirement is greater but is also of this order of magnitude These are very small amounts Our D requirement is only about 1/300,000th of our calcium requirement—quite a bit smaller, as anyone will realise who has looked round the crowd at Twickenham during the interval of the Calcutta Cup match, but large enough to exert a profound influence upon it. Yet if our daily dose of D were made up into pills the size and weight of a red blood corpuscle we should have to take 30,000 pills a day 20 pills a minute all round the 24 hours

These calculations may seem mere frivolities, and admittedly they are only a variation on the old adage about big fleas having lesser fleas, but it may comfort some to realise that these lesser fleas have concrete sizable proportions and we need not proceed ad infinitum to visualise them

Annotations

PLASMA FILTRATION

AN essential step in the preparation of citrated plasma suitable for storage as a blood substitute is its clarification and sterilisation by filtration through asbestos pads Unfortunately this presents considerable practical difficulties, since passage through the filter induces clotting Bushby and Whitby[1] suggested by way of explanation that, in the presence of magnesium ions from the asbestos, thrombin is formed from prothrombin adsorbed on the pads, and this leads to clotting They believe that washing the pads with dilute alkali at intervals during filtration removes adsorbed prothrombin before its conversion to thrombin, since clotting of the filtrate is reduced It is not however abolished, and larger or smaller clots usually develop during storage in bottles of citrated plasma filtered in this way In some cases it is then difficult to decide whether a given bottle is contaminated or sterile, and it is always necessary to include a filter in the equipment used for transfusion Bushby and Whitby[2] have now shown that if citrated plasma is made decidedly alkaline before filtration the filtrate does not clot, and they conclude that thrombin is not formed under these conditions The excess alkalinity of the filtrate can be neutralised with carbon dioxide under pressure, so that the final product has the almost neutral reaction of the blood Clinical tests of citrated plasma filtered by this method have proved satisfactory, and there is no chemical evidence of damage to the plasma proteins by the somewhat drastic incidental alkalinisation The new method is more rapid and less wasteful than the earlier method, but cannot of course compare in simplicity with the filtration of serum It is the possibility of preventing the entire waste of time expired citrated blood by recovering plasma for storage which justifies persistence in plasma filtration Since, however, most of the bottles of citrated blood now collected contribute ultimately to blood-substitute stores, it might seem wiser to collect clotted blood and store serum, maintaining the banks of citrated blood at that level which the experience of the Transfusion Services has shown to be necessary Not only would the difficulties of plasma filtration thus be avoided but the stored product would be cleaner, since it is said[3] that at least 5% of bottles of blood collected are contaminated and hence should be processed without delay

FAMINE RELIEF

THE food blockade of the continent is a blunderbuss which by definition does execution at short range without exact aim Designed to starve our enemies into submission it helps to starve our friends in enemy-occupied countries The Famine Relief Committee, formed as a result of two conferences of church leaders called by Dr G K A Bell Bishop of Chichester, in the spring, has collected evidence on food conditions in Europe[4] Famine is acute in Greece, where 320,000 deaths—five times the normal death-rate—were registered from August, 1941, till the end of March, 1942 Before the war 40% of necessary foodstuffs were imported into Greece, in December the average daily consumption of bread had been reduced from the normal 27 oz to 2½ oz or less In January 900 deaths a day from famine were reported, children are naturally most affected, and were unable to resist epidemic diphtheria which swept Athens and the Piræus In Belgium cases of starvation œdema are appearing, and scurvy, rickets, anæmia, dermatosis and eye infections are becoming common Of children attending school two-thirds get hardly any breakfast, and a third get an inadequate midday dinner The teachers cannot hope to maintain scholastic standards because the children are too apathetic to attend In unoccupied France conditions are comparable with those in Europe in 1918, the infant mortality-rate increased 45% between 1939 and 1940 In occupied France the official rations exist only on paper, and only in the rural districts is it possible to maintain a reasonable standard of living Rations allowed to the Poles are on a starvation level and the Jews in Poland get less still. The committee, which is under the chairmanship of Dr Bell and has Miss Pye as its honorary secretary, includes representatives of every section of Christian and Jewish thought in Great Britain They plan, in coöperation with existing organisations to send food, vitamins and medical aid into occupied countries wherever control is possible This is not a fantastic undertaking, for in January, 1941, Germany guaranteed that no deduction for the benefit of armies of occupation would be made from shipments destined for necessitous people in occupied territories, and this guarantee seems to have been fully observed Thanks to negotiations carried through by the British Government 4000 tons of food a month is reaching Greece through Turkey The American Friends Service Committee is giving supplementary school meals to 85,000 children in unoccupied France and is also supplementing feeding in refuge camps The Commission for Polish Relief has been able to carry out controlled relief, 50,000 children being fed for 18 months, the Polish foreign office is satisfied that none of this food was taken by the Germans The new Famine Relief Committee is anxious to see an informed public opinion in this country which will be ready to face the difficulties of controlled relief Several important bodies including the Church of Scotland General Assembly, the Baptist Union of Great Britain and Ireland, and the Cambridge United Council of Christian Witness, have already

Syme stump was that no artificial limb could be fitted to conceal the disablement—and they contend that the man who has had his leg off must be made to walk, act and look as if his limb was absolutely normal[8] Few could argue with the ministry, for not many surgeons did enough amputations, and this teaching came to be accepted Of late the Canadians, led by **Gallie**[9] and **Le Mesurier**,[10] have asserted that the surgeons of the ministry have been too hard on end-bearing stumps, in particular Syme amputations In Canada the government also had a follow-up after the last war and over 2000 amputations have since been under constant supervision Out of 53 Syme amputations, including 1 double, 7 needed subsequent minor operations such as removal of a neuroma, but not a single one has had to be re-amputated since 1922 Of these cases 20 have had their amputations for over twenty years, but their stumps show no œdema or circulatory disturbances and they can "stand and walk all day, follow the plough and work in the factory" The Canadian artificial limb for a Syme amputation differs slightly from ours in that the stump end is completely enclosed, the stump sits in a metal cup and a blocked leather bucket extending up from it is so shaped that the upper part takes some tibial bearing

The low opinion of Syme's amputation does seem to need revising At present, as **Le Mesurier** points out, anyone doing a Syme amputation is liable to find it re-amputated by someone else It would be a pity if the operation was no longer taught in medical schools There can be no doubt that for the agricultural labourer, and wherever expert mechanical-limb centres are not available—a large part of the globe—the Syme amputation is the method of choice, to do a day's work a man need merely shove his stump into an easily made broad boot A peripatetic correspondent[11] with the Chinese forces mentions this difficulty of obtaining artificial limbs and says that out there every effort is therefore made to avoid amputations A Syme amputation is not something to be rushed in the heat of battle, for sepsis spells certain failure for the stump Indeed in war, unless circumstances are particularly propitious, immediate amputations through any site of election are undesirable Amputation by flaps at the site of injury is the wiser choice, and the final amputation is a plastic procedure to be settled later **Huggins**,[12] after extensive experience of amputations in the last war, laid down that the optimal time for re-amputation is when all œdema in the skin and deeper structures has subsided—usually after about four months **Le Mesurier** maintains that a Syme must not be done above an inflamed wound, since the lymphatics are infected and sepsis is inevitable, nor for an arterio-sclerotic lesion or one following cold or immersion Attention to the details of the operation is particularly important To prevent the flap slipping to either side or backwards careful strapping is required, it is probably the only amputation where nerve shortening is desirable Despite drainage a hæmatoma will sometimes form, and immediate postoperative pain in the stump is often a sign of it **Perkins**, in a lecture at the British Postgraduate School, advised that in all amputations if a hæmatoma is diagnosed you should "pocket your pride, take the patient to the theatre and evacuate the clot" A failed Syme is not a disaster, nor is it a reflection on the surgeon, who in modern war has to handle severely mutilated tissue But a failed below-knee amputation is a tragedy for the patient, and a primary tibial amputation at the site of election, performed for a foot injury, carries a heavy responsibility Even under the best conditions the below-knee amputation does not invariably stand up to full wear, and an increasing number—10% at present—have to be fitted with ischial bearing corsets The outstanding disadvantage of the Syme amputation is the ungainly artificial limb But for a man handsome is as handsome does and most of the limb is concealed by his trousers For the woman ungainliness is undoubtedly a strong argument for a tibial election-site amputation, though it is surely not beyond the ingenuity of the makers to fashion a more shapely limb for the modern type of Syme amputation

HOW BIG OUR SMALL NEEDS

Appreciation of size and weight is a question of comparison and familiarity Housewives think in terms of pounds and ounces and have a good idea of the value of each in terms of foodstuffs We all know how many pennies it takes to make a trouser pocket uncomfortably full and heavy, and how many gallons are required to top up the tanks of our cars—but change the units and we are lost Many who took a car to the continent in the old days will recall their confusion when they first had to buy petrol in litres There may be still worse difficulties if the mind is called on to appraise a greater range of size or weight or distance than is usual in everyday life—the National Debt would be a poser to most people who visualise it in terms of their own salary, and the difficulty of grasping astronomical magnitudes has become a popular gambit Few of us have even tried to size up our vitamin and mineral requirements in terms of our daily food Here things are further complicated by the multiplicity of units and methods of expression, there are parts per million, gammas per gramme, mg per 100 g and so on Workers in these subjects, moreover, make a point of emphasising the minute quantities of the substances which they can handle and which may be necessary for life, so that many doctors have resigned themselves to feeling that appreciation of the size and weight of "traces" is beyond them They have lost, in consequence, a great deal of the interest attached to the recent work on nutrition

Most people find it a help to get the data with which they are confronted into concrete terms or at any rate familiar units Sometimes it helps to think of things in terms of oneself A man is about 1 part per 100,000 of a big football crowd, or 1 part per million of the weight of the *Queen Mary* Others find that 1 part per million, or 1 gamma per gramme, can be made understandable by calling them 0 1 mg per 100 c cm Others again employ some standard of comparison such as a red blood corpuscle with which they are familiar A glass of water, for example, containing 6,000,000 red blood corpuscles may be regarded as particles appeared more dense than usual no internal structure being visible. This suggests that some of the antibody remained attached to the virus particles. A somewhat similar finding in the case of bacteria indicates that soon more light may be thrown on the reaction between viruses and their antisera. It was not possible to designate the limiting structure which separates the virus from the surrounding medium as a semipermeable membrane. Green and his co-workers only say that the surface of the bodies appeared to be different from the main internal constituents. Ruska does not think that the viruses of variola rabbit myxoma and ectromelia possess a membrane similar to that of the bacteria. However it seems certain that vaccinia virus has a morphological structure which in many respects approaches that of bacteria and differs from that of the plant viruses. This technique may later reveal such interesting facts as a difference in structure between freshly isolated strains and those long passaged in mammals or attenuated by passage in the developing chick embryo.

GASTRIC ACTIVITY AND FAT DIGESTION

THE action of fats on gastric digestion is peculiar but is slowly being clarified. It is now established that ingestion of fat will inhibit both motor and secretory activity of the stomach—the latter including both enzymes and acid, and affecting both chemical mechanical and psychic ' secretion. Ivy and others have shown that this inhibition is at least partly dependent on an inhibitory hormone known as enterogastrone which released from the duodenal mucosa when fats or fatty acids reach that area is absorbed into the circulation and thence depresses gastric activity. Quite why such an inhibitory mechanism exists is not yet apparent, but some recent experimental work of Tidwell and Cameron[1] suggests that it varies with the chemical composition of the fat ingested. Working with cats and rats these investigators found that the more unsaturated fats tended to remain longest in the stomach, while the more saturated ones tended to cause least gastric inhibition and to get further down the intestinal tract in a given time. For instance, while 43% of a dose of olive oil could be recovered from the cat s stomach at the end of three hours only 25% of tripalmitin, but as much as 71% of linseed oil could be found there after the same period. Similarly, whereas after three hours much of the palmitin was found in the cæcum none of the linseed oil had by that time reached so far. In observations on one infant given a barium meal containing various types of fat they again found that the gastric emptying time when olive oil was used was more than twice as long (5½ hr) as when a palmitin and stearin mixture was given (2 hr). From these results Tidwell and Cameron suggest that gastric inhibition is probably induced by the actual absorption of some fat from the upper intestine rather than by any purely physical properties of the fat itself. Thus they conclude from their findings that fat structure, fat absorption and gastric inhibition run—remarkably parallel—with saturated fats the intestinal absorption is more rapid as the carbon chain is shortened and the more readily fats can be split the greater their absorption rate. The mechanism would thus depend in their view on the intestinal enterogastrone being liberated into the blood stream only on actual absorption of some fat from the duodenum and not merely on the entry into the duodenum of fat as such, thus the more rapidly some absorption can occur the more quickly and completely will gastric inhibition take place. The exact part which this mechanism plays in the processes of digestion and its precise applications in clinical medicine are far from clear. Whether the inhibition is merely a safeguard against fats (and other foods) entering the intestine more rapidly than they can be absorbed or whether it is bound up with the acid-alkaline reactions of stomach and duodenum is not known. Certainly gastric emptying time and secretion are delicately balanced and highly adjustable processes and their relation to the varying types and quantities of foods eaten is one of the factors on which the whole mechanism of digestion—and indigestion—depends. More work on these lines should help in the treatment and prevention of both major and minor dyspepsias.

INFANTILE RICKETS IN AUSTRALIA

DISQUIETING evidence of the occurrence of rickets in 47% of a group of full-term infants at some period in the first year of life is reported[1] by F W Clements from the Australian Institute of Anatomy Canberra. It is disquietening that the prevalence of rickets should be so extensive in a land richly provided with sunshine and all the more so when it is appreciated that the source of the material for study was the infant welfare centres of the Canberra Mothercraft Society where the very poor are not found "and the percentage of under-privileged is small". During the past 2½ years nearly 500 infants have been seen and examined radiographically for rickets. Of these 150 have had radiograms taken regularly each month during the first year of life and of 134 full term infants who had completed this examination 63 or 47% showed definite evidence of mild rickets during the first year of life. Eight premature infants in the series all showed rickets. A child was considered to have suffered from rickets if one radiogram was obtained showing definite rachitic changes. ' Doubtful appearances that became normal in the next radiogram were not included as positive. In 80% the onset of rickets occurred before the sixteenth week. Connecting the radiographic findings with certain clinical aspects of the subject Clements reaches certain tentative conclusions. For example as regards bony deformities it is recorded that 3 to 4 months after the rickets had healed the bones appeared to be normal, but it is proposed to follow these infants for some years for the possible development of knock-knee bowleg and certain changes in the shape of the chest wall. A similar follow-up study will be made as regards the state of teeth. When the rickets persisted for more than three months some of the classical clinical signs appeared particularly epiphyseal enlargement and hyperplasia of the costochondral junctions. Growth was not essentially affected unless the rickets lasted for four or five months. The infants appeared heavier than they actually were and looked pale, although hæmoglobin determinations showed no anæmia. Cranio tabes was not found in this series. Indeed Clements insists that the mild rickets he detected radiologically does not give rise to sufficient clinical signs to make diagnosis possible except by X rays until it has persisted for more than three months. An analysis of the factors responsible for this high prevalence of mild rickets suggests that the calcium intake of the mother coupled with adequate absorption of the calcium is the most important. Postnatal feeding of the infant (and even of the mother in breast-fed infants) is also important, and it is not enough that the infant shall obtain enough calcium. ' It is imperative that there shall be enough vitamin D in the body of the infant to ensure the highly efficient absorption of the calcium from the alimentary tract." Clements doubts if enough vitamin D can be developed by regular exposure to the sun and to prevent rickets this substance must be taken by mouth. Clements makes certain important recommendations as a result of his studies. Every expectant mother must have adequate calcium in her diet—secured by at least 1 *pint of milk* daily or large doses of calcium lactate or gluconate (120 grams of calcium lactate are equivalent in calcium to advocated such relief The committee suggests that regular and adequate supplies for Greece must have first place, In order that our Government may have evidence of public feeling the committee advises those interested to form local groups of sympathisers, to get people whose names will carry weight to write letters to the local press, and to arrange deputations to members of Parliament Mr Dingle Foot's recent statement[5] in the House of Commons sets out the directions in which it has already been possible to mitigate the effects of blockade At present no stocks of food may be collected in Britain for relief, but the committee has decided to open a fund to be used for help in the invaded countries as soon as permission is granted , if permission is withheld until the end of the war, it will be used then for immediate help and reconstruction

[1] *Med J Australia* 1942 i 336

Two instructive booklets written for the Royal Institute of International Affairs, one on postwar relief in general[6] and the other on medical relief,[7] urge the need for setting up international relief machinery now so that it can be put in motion directly the war ends When the last war ended there was a year of chaos in which vast numbers of people died from malnutrition and preventable disease on the continent before effective relief measures could be applied The machinery might be controlled by either the Office d'Hygiène Publique at Vichy or the Health Organisation of the League of Nation at Geneva The former, unluckily, is now largely German controlled and has no personnel for relief work The Health Organisation has already done extensive relief work in many of the distressed countries and its experience and the nucleus of its medical staff which still remains could perhaps be used at once when the war ends It may however be better to set up an entirely new organisation with a commissioner and an advisory committee including representatives of the public health services of each country. Fortunately it is not difficult to foresee what forms of medical relief will be required and a start should be made now to work out the details, as well as to build up a store of food and medical supplies The first step is to decide on a central administrative body which will ensure that this time the efforts of voluntary and official organisations are not squandered through lack of coordination Dr Mackenzie also demonstrated that it is not too soon to plan the outlines of a permanent international medical organisation, though the problems it will have to face can as yet be only dimly discerned

ANISEIKONIA

PEOPLE who have a different refractive error in their two eyes see ocular images of unequal size For instance, if one eye is myopic and the other hypermetropic, the image in the latter will be the larger of the two, for a convex lens magnifies and a concave lens minifies Provided that the disparity is not too great, these people achieve stereoscopic vision, though perhaps with some symptoms of strain In 1935 Professor Ames,[8] working on physiological optics at the Dartmouth Eye Institute, Hanover, New Hampshire, reported that there was often a disparity in size of the optical images even in isometropia To this difference, which could not be accounted for by refractive error, the term aniseikonia was applied The difference was usually only 0 25–0 5%, but in people complaining of asthenopia it might be 1 5–1 75% To diagnose the condition he invented the tipping table and an instrument named the eikonometer, and he prescribed special lenses for the condition No exact figures of cases are yet available, but it seems that a third of his cases are relieved of their symptoms while another third report partial relief Field,[9] of the North Western University medical school, finds, as one might expect, that most of the patients referred to him for aniseikonia were in need of more adequate refraction and investigation of their muscle balance and convergence powers Until more convincing evidence is forthcoming most ophthalmologists will agree with Field that aniseikonia is not a common cause of asthenopia It must be remembered that there are always some patients who will be relieved by the psychological effect of a lengthy investigation with elaborate instruments and the subsequent prescription of an expensive pair of glasses

STRUCTURE OF VACCINIA

SLOWLY some of the mysteries of the viruses are being unravelled while others tend to become more complicated It becomes increasingly clear that their properties as viruses are so divergent that generalities must be avoided They range in size from those of vaccinia, myxoma, canary pox, lymphogranuloma venereum and rabies, all between *125 and 175 $m\mu$ in their* largest diameter, down to poliomyelitis (human and mouse) at about 12 $m\mu$ and foot-and-mouth disease at about 10 $m\mu$ The viruses of lymphogranuloma venereum and a new mouse pneumonitis virus are susceptible to the action of the sulphonamides and thus so far different from all the rest Vaccinia, one of the largest and most highly organised of the viruses, has been intensively studied by Hoagland and his colleagues[10] They found that the elementary bodies of vaccinia are composed chiefly of protein, thymonucleic acid, lipid and carbohydrate in concentrations not much different from those found in bacterial cells They have since found small amounts of biotin and riboflavin present In purified suspensions they have also found a copper constituent in a concentration amounting to 0 05% of the dry weight of the virus , a 25-fold increase occurring during purification of the virus In contrast to this Sprince and Schoenbach[11] have failed to demonstrate significant amounts of riboflavin, pantothenic acid and biotin in moderately concentrated solutions of purified tobacco mosaic virus which is only about 1/5 the diameter of that of vaccinia The elementary bodies of vaccinia have also been shown to respond to osmotic influences and to be antigenically complex The use of the electron microscope has given new opportunities for observing any structural difference that may help to explain their action and differentiate between the bacteria and viruses Von Borries and the Ruskas[12] in their original experiment found the virus particles of vaccinia somewhat oval in shape and uniformally opaque Green, Anderson and Smadel[13] have obtained the same picture with unwashed stored preparations of vaccinia but when these were rewashed immediately before use *they* presented a high degree of regularity of external outline and internal form The particles are almost rectangular in shape, resembling a brick, and contain five areas of condensation, the central one being slightly larger than the remaining four Heating for an hour at 56° C , dehydration in a vacuum over P_2O_5 and drying from the frozen state did not appear to alter the internal structure The various stages of dissolution by alkali treatment, ranging from swelling, blurring of the edges and decreasing density of the substance to complete laking, could be clearly seen After exposure to hyperimmune vaccinia rabbit serum, the rewashed

DIGESTIBILITY OF NATIONAL WHEATMEAL

NORMAN C WRIGHT, D SC OXFD, PH D CAMB
DIRECTOR OF THE HANNAH DAIRY RESEARCH INSTITUTE
KIRKHILL, AYR

ACCORDING to a statement attributed to Drummond (1942) the Ministry of Food were largely influenced by considerations of digestibility in advocating the adoption of the national wheatmeal loaf It is therefore important that reliable figures should be available as a basis for comparing the digestibility of national wheatmeal with that of straight-run white flour

Krebs and Mellanby (1942) recorded experimental results which cast some doubt on the validity of the figures used by the Food (War) Committee of the Royal Society (1917) and by myself (1941) in calculating balance sheets of the gains and losses of nutrients resulting from the raising of the extraction level of wheat Unfortunately Krebs and Mellanby's experiments are open to serious criticism in both design and execution In the first experiment the national wheatmeal used contained only 0 45% of fibre, against the standard of 0 60–0 85% suggested by the Accessory Food Factors Committee (1941) and a mode figure of 0 85% on 303 samples examined by the Research Association of British Flour-Millers (1942) In view of the well-recognised relationship between fibre content and digestibility, the use of the low fibre sample by Krebs and Mellanby clearly makes their results inapplicable to ordinary national wheatmeal Moreover they state that the white flour and national wheatmeal were derived from different grists This too, obviously lessens the value of their work, since variations are known to be very wide in the quality of individual consignments of wheat

This error was also made by Wood (1941), who compared a ample of white flour from one grist with samples of three igher extraction flours from another grist As a result, the gures for the digestibility of the white flour sample failed to all in line with those of the other three flours (see graphs) Krebs and Mellanby have failed to note this, and in conseuence wrongly accuse me of misquoting Wood's figures

n their second experiment Krebs and Mellanby did not n fact compare the national wheatmeal with white flour at all an attempt was made to arrive at a digestibility igure by comparing the fæcal output of a "control" diet of meat, fish, margarine, bacon, cheese, milk, potatoes, and mixed vegetables, with that of a diet in which unlimited quantities of national wheatmeal bread replaced half the mixed food intake In the control period the energy intake was 1850 calories per day in the experimental period 3450 calories per day, while the protein content of the experimental period was over double that of the control period Moreover the final calculated digestibility was not merely compared with that of a white flour derived from a different grist but with a figure arrived at by Macrae and his colleagues (1941) in an entirely different experiment of entirely different design The results obtained by individual workers vary so widely that such a comparison is meaningless

If, then, the results recorded by Krebs and Mellanby cannot be accepted what basis of calculation should be used in comparing the digestibilities of national wheatmeal and white flour ? A review of the relevant literature over the past 40 years indicates that a reasonably sound basis can be arrived at without further experimental work The object of the present article is to summarise the results recorded over this extended period and to attempt to establish acceptable figures

PERCENTAGE DIGESTIBILITY

The experimental methods adopted in most of the earlier work were similar consisting of the direct substitution of one type of bread for another in a diet of otherwise constant composition The analytical methods used were essentially those still employed in such work the Kjeldahl method for total nitrogen, and a bomb calorimeter or calculation from the total proximate constituents for total energy The types of flours used by different workers varied widely however Wood (1911) used flours of 70%, 80% 88% and 92% extraction, while Rubner (1918), whose experiments were specifically concerned with Germany's war-time bread supply, used flours of 70%, 80%, and 95% extraction Hamill (1911) based his conclusions on a thorough review of earlier American work which dealt in the main with white flour so-called entire wheat flour, and Graham (wholemeal) flour "Entire wheat flour" appears from Hamill's description to be similar to the present-day national wheatmeal The Royal Society Committee's Report (1919) was concerned with two levels of extraction—78% and 88% The work of Macrae and his colleagues was also carried out with flour of two extraction levels—73% and 100% It will be seen, therefore that the collected results cover a wide range of extraction levels and refer to work carried out in widely different localities and at varying dates

An examination of these collected results shows that, while the *absolute* levels of digestibility varied widely from one set of experiments to another all workers have recorded a considerable fall in digestibility with increasing extraction The extent of this fall is shown in the graphs, in which the collected results have been plotted on a composite diagram after conversion to a common basis For this purpose the digestibility of 70% extraction flour has been arbitrarily taken as 100% and the remaining values have been recalculated in proportion[1] The two graphs show clearly that all the curves fall as the extraction level rises, though the rate of fall varies widely with individual workers, the variation being greatest for the protein values From these collected results it is possible to arrive at representative mean percentage reductions per unit increase in extraction level The figures work out at 5% reduction in protein digestibility and 4% reduction in energy digestibility for each 10% increase in extraction If such figures are applied to the mean absolute values of digestibility of white (70% extraction) bread, the results noted in the table are obtained These values may be compared with the American figures recorded by Hamill for white flour and for the same flour with finely ground bran added, a mixture which might reasonably be compared with national wheatmeal Hamill's figures of percentage digestibility which agree closely with the mean values are as follows

MEAN VALUES OF DIGESTIBILITY

Extraction level %	Percentage digestibility Protein	 Calories
70	*88*	*94*
75	85 7	92 1
85	81 4	88 4
Difference	4 3	3 7

	Protein	Calories
White flour	90 9	92 1
" " plus bran	85 9	87 6
Difference	5 0	4 5

In general, the protein digestibility values recorded in the table show a significantly smaller difference than those which formed the basis of the Royal Society's original estimate and of my own calculations (89% and 81%) but a significantly larger difference than those recorded by Krebs and Mellanby (91% and 89%) The energy values closely approximate to our figures which were 92% and 87% respectively, but again show a slightly larger difference than those of Krebs and Mellanby (97% and 94%)

PROTEIN AND ENERGY CONTENTS

In arriving at the total digestible nutrients contained in the two types of flour it is however, at least equally important to take into account the relative contents of total protein and energy As with the digestibility values, it is admittedly not easy to arrive at typical representative figures As regards total protein, the mean values recorded in Hamill's review work out at 12 07% and 12 57% for white flour and wheatmeal respectively—a difference which agrees closely with that calculated from the analyses given by McCance and Widdowson (1940)—that is, 11 0% and 11 5% At the

---

[1] The figures given by the Royal Society relate to the digestibilities of the diet *as a whole* and not to the bread alone To obtain comparable figures for the various types of bread the results require recalculation Wood's published figures for energy relate to percentage utilisation and not to actual digestibility for the latter values recalculation is necessary The figures used in the present paper are in both cases the recalculated values

1 pint of milk) Equally important is the absorption of this calcium and vitamin D must be given to the pregnant woman For postnatal prevention every infant, including the breast-fed, must receive vitamin D by mouth as early as is practicable It is doubtful whether enough cod liver oil can be given to the very young infant without upsetting the digestion, and Clements therefore advises a vitamin-D concentrate in a dosage of about 400 international units per day

CONTINUOUS SPINAL ANÆSTHESIA

ANY method of anæsthesia which depends on the single injection of the whole dose has disadvantages People vary in their susceptibility to drugs and a dose just sufficient in one person to maintain the right level of anæsthesia for the required time may be excessive for another person In order to overcome this obstacle W T Lemmon and G W Paschal[1] have devised a technique for carrying out what they call serial fractional controllable intermittent spinal anæsthesia , and in an account of a series of 1000 operations they make out a very good case for the procedure Naturally, since the needle has to be left in position throughout the operation, a special needle and a special mattress with a gap in it are needed in order to avoid all possibility of breaking the needle Stout small-bore tubing 30 in long connects the needle with the syringe which has a Luer Lok plug to meet the stopcock on the tubing and prevent any escape of cerebrospinal fluid The authors use procaine hydrochloride ('Novocain'), dissolving 500 mg in 10 c cm of CSF of which 2–3 c cm are introduced into the subarachnoid space when the stopcock is closed During the induction period the patient is kept in 5° Trendelenburg position If after 10 min the degree of analgesia is not enough an additional injection of 1 c cm is made, and other supplementary injections are made whenever necessary in the course of an operation Lemmon and Paschal find it takes about 90 sec for the added dose to exert its full effect In long procedures they give the supplementary doses at fairly regular intervals, usually every 30 or 40 min As preoperative medication they always give phenobarbitone on the night before operation as well as 3 hours before it, and also an injection of morphine and scopolamine If necessary they repeat the morphine injection in the course of the operation either intravenously or subcutaneously The average length of operation in the recorded series was 50 4 min , but one gastrectomy took over 3½ hours The average dose used was 220 mg though with operations above the diaphragm the usual dose needed was much higher than this, being 445 mg A 5% solution made by dissolving the procaine crystals in the cerebrospinal fluid was found to be the most satisfactory strength There were no deaths attributable to the anæsthetic, but headache and pulmonary complications were about as common as they are after the usual spinal methods

CHRONIC STREPTOCOCCAL ULCERATION

F W Taylor[2] has found the hæmolytic streptococcus as the infecting organism in a series of cases of chronic ulcer of the extremities, and believes that this is a type of ulceration too little recognised because it is unsought , it responds dramatically to sulphanilamide by mouth The ulcer is a distinct entity, not associated as a rule with vascular impairment Children and young adults are mostly affected, the initial lesion being a slight cutaneous trauma such as an insect bite, not specially painful The ulcer is indolent with slight surrounding reaction The fact that the lesion is so chronic and is unassociated with lymphangitis or œdema is likely to prevent the surgeon suspecting its hæmolytic streptococcal origin The organism is obtained from the ulcer in pure culture or may have a contaminant, such as *Staphylococcus albus* The lesion is quite distinct from the burrowing ulcers described by F L Meleney Its margins are reddened and may or may not be undermined, while the base is covered with pale granulation tissue which exudes a watery serum Among 31 cases in Taylor's series all but 2 appeared on the lower extremity, but two children showed several ulcers over the dorsum of the hand and arm The ulcers ranged in diameter from 1 cm to 6 cm , had been present from two weeks to four years, and had been treated with a great assortment of external applications Treatment with sulphanilamide was mostly carried out in outpatients The dose given to adults was 1 3–6 g by mouth daily Doses of 4–4 5 g daily were sufficient, but smaller doses were on the whole ineffective Only 19 of the 31 cases received adequate doses , these ulcers all healed, whatever their previous duration, in an average of just under a fortnight, and they remained healed Taylor is now experimenting with local application of sulphanilamide, which he thinks should give good results

EMOTIONAL LEUCOCYTOSIS

THAT infection is not the only cause of leucocytosis has often been noted[1] , one of the most curious of these non-infective leucocytoses is that associated with emotion A high white cell count is not an uncommon finding in mental patients and the reasons advanced have been fever, dehydration, or some obscure infection Wittkower[2] showed that leucocytosis could be caused by suggesting various emotions to hypnotised patients, this and similar investigations did not support the infection theory Milhorat, Small, and Diethelm[3] have now studied the problem in mental patients They took special care to use accurate methods to get as near basal conditions as possible for the "resting" counts, and to avoid well known traps like diurnal variation In their group of 200 patients, 34 had infectious diseases which were likely to affect the white cell count and 15 of them had counts of over 10,000 per c mm , excluding these, 26 5% had white cell counts over the 10,000 per c mm mark These leucocytoses were not limited to any particular mental disease but they were clearly related to the emotional state of the patients The behaviours most often associated with leucocytosis were 'panic reaction, depression with agitation, excitement with over activity and anxiety, and excitement with overactivity and elation " Sadness without anxiety, and elation without anger, were not accompanied by leucocytosis Counts up to 21,000 per c mm were registered but the differential count did not vary No evidence of dehydration with consequent blood concentration was detected Further evidence was provided by giving the patients intravenous 'Sodium Amytal' in doses sufficiently large (0 3–0 5 g) to produce definite symptoms like slurring of speech , these doses were followed by mitigation of the exaggerated emotional state, and there was a corresponding fall in the elevated leucocyte count When the leucocyte count was not raised, sodium amytal did not affect it, though the emotional changes were induced just the same Sodium amytal was also given in the same dose to a patient with non emotional leucocytosis and although the narcotic effects appeared as usual the white cell count remained raised Milhorat and his colleagues attribute this emotional leucocytosis to a redistribution of leucocytes from the reservoirs in collapsed capillaries of resting muscle, liver, lungs and spleen brought about by the circulatory changes which accompany emotional reactions , as adrenaline is known to produce leucocytosis they suggest that this hormone has a part in the reactions In all this they are in line with and confirm previous views

In England Now

A Running Commentary by Peripatetic Correspondents

THE peripatetic who suggests "homo alternans" as a suitable generic name for mankind doesn't think a whole lot of us medical planners Well, it is only fair to say that some of us don't think a whole lot of him If he is not prepared to believe that, by taking thought, man can add a cubit to his material and moral stature, he will find a formidable array of hard fact and enlightened opinion ranged against him The real subconscious (his word, not mine) argument against medical or any other kind of planning is that it is hard work, not only does it demand the acquisition of a great deal of information, some of which may be very distasteful to one's personal prejudices and cherished beliefs, but it also entails much critical and self-critical, constructive, and imaginative thinking Why must all planning be pro-bureaucratic and anti-individualistic? Does he really suppose that we are not considering the points of view of the warriors or that there are no planners among them? Does he assume that all these young men and women in the Services are so delighted with the world as it is or with medicine as she is practised that their one hope is to see her stay as she is for ever? And what about the 40 odd millions of patients, actual or potential, in these islands, are they all quite satisfied that they get the squarest possible deal when they are ill? All planners have always made, are making and will continue to make "enormous and manifold errors" and miscalculations, but the fact that we failed to create a new heaven and a new earth after the last war does not strike some of us as an adequate reason for not trying again And despite the jeremiads, the cynicism (which Pasteur, I think, called sterile) and, worst of all, the resignation of the sub-group homo automaticus, try again we will

* * *

Now that the crowds have melted, the President of the Board of Education is back in London, and they are pulling down the centenary bunting we may creep out and examine with a little detachment that awesome, Jehovah-like figure with side-whiskers, deep-set eyes, and protruding lower lip, Thomas Arnold, 'zealous, beneficent, firm" Mr Butler said that had he been alive today he thought he would have approved of the educational reforms contemplated by Mr Butler This claiming as an ally somebody who is dead or not yet born like "the historian of the future" is all nonsense In the unlikely event of the same dynamic, one might almost say original Thomas Arnold reaching the age of 147 it may be safely said that he would not have approved, but fought like a tiger for these reforms 50 years ago What he would be fighting for now is not vouchsafed to us it would be 50 years ahead of our present ideas, for we have the myopia of mediocrity When one remembers that "this champion alike of reverent faith and independent thought" very nearly had his career as a schoolmaster wrecked by scurrilous Tory attacks on his liberal opinions in social and theological matters I think it exceedingly doubtful whether he would have approved of Mr Butler or Mr Butler of him He was the antithesis of a yes-man, a big, capital No-man In fact he would have made the last 50 years very uncomfortable for many of us "sternly repressing the bad," entirely for our good Like the mammoth, who may have taught man how to sprint, he was a great benefactor

Which brings one to the obvious but little understood question of leadership in democracy The real leaders are, of course, the Press, the Pulpit, and the Prevailing Wind—that is to say original thinkers or strong characters or conglomerates They put their views into circulation and after 1–50 years the people say, "That's rather a good idea, let's do it" Then they look round for some rather compliant individual and say, "Look here, you've got to go to Parliament and do this for us" That's why it's silly to think of political heads as leaders It only rarely happens that strong characters can get the approval of Demos Then it is as a rule on other than political grounds, hence the PM In war-time matters are different, but one must not expect too much from the housemaid Another schoolmaster who was a leader in the true sense, 50 years ahead of his time, who has done more perhaps for positive health than anyone in the last hundred years in this island except B-P, was Almond of Loretto His ideals of hardiness and simple dress have been followed not only in this country but all over the Antipodes Last week going through Pangbourne I was glad to see they have adopted the Loretto style at the Nautical College, now under an old Loretto boy It is rather surprising that there haven't been more headmaster leaders when one thinks of their opportunities of platform and constant stream of potential disciples The reason, I think, is that most of them have been chosen for scholarship a habit of word-thinking that cramps the vision, makes for stasis and orthodoxy, a form of specialisation from which few return, an irreversible addiction

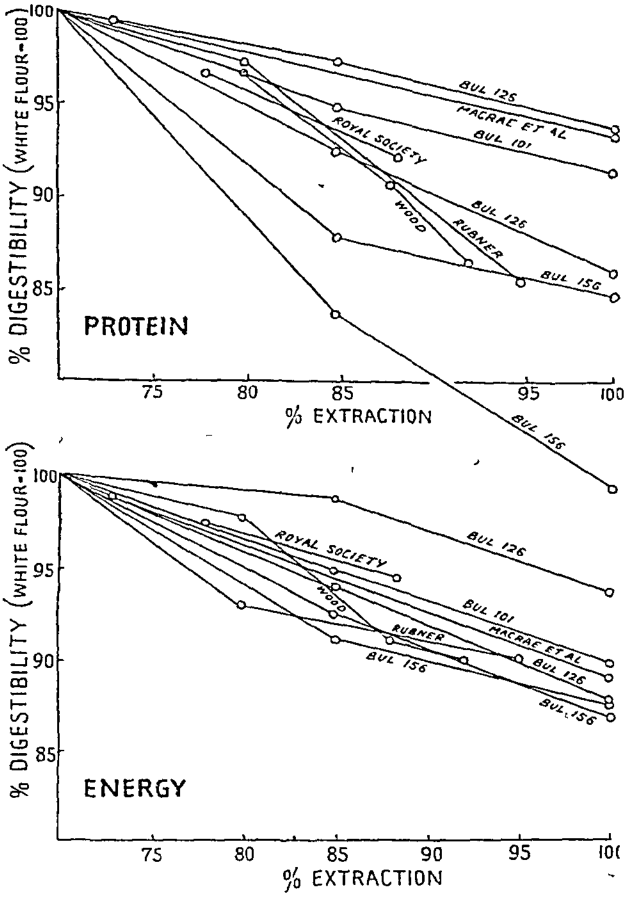
* * *

The medical transport officer put down his fourth glass of gin "Thanks very much" he remarked "I'll send those six cot cases and five walking cases over before the ship sails and I should keep an eye on three of them, they're a bit barmy" With that he departed and I rang up the sick bay to tell them what to expect, and that I would inspect them in the dogwatches I sat down to lunch with the pleasant anticipation of getting my head down for the afternoon At 14 15 I was rudely awakened by my sick-birth chief petty officer He carried in his hand a well-thumbed copy of King's Rules and Instructions and with a sinking heart I saw his thumb on the part about the duties of the senior medical officer With a further sinking I saw he had his leading sick-berth attendant with him and that he in his turn was loaded down with Admiralty Fleet Orders The MTO's remarks "three of them may be a bit barmy" suddenly came to my mind and we were three hours out of harbour All too soon I was buried in orders AFO 7932/22 was intensely depressing and seemed to indicate that ratings suffering from mental derangement should be under the constant eye of a medical officer AFO 17532/26, however, was more cheerful and without doubt threw the whole onus on the captain of Marines The little procession now headed by myself proceeded to the captain RM's cabin and to our delight we found he had his head down also With considerable adroitness he parried every thrust until I pressed home with AFO 17532/26 He was a beaten man and the issue was no longer in doubt Nine Royal Marines duly appeared in the sick bay and divided themselves into three watches The isolation ward became our mental ward and for the rest of the voyage it rang with the delighted laughter of the escort and the dry remarks of our lunatics who were obviously highly enjoying themselves The voyage continued peacefully, and our patients became the life and soul of the ship During their spells of exercise on the fo'c'sle, they were more often than not the centre of a happy throng, and the captain's remark that "If those are lunatics the rest of us are stark raving mad" sounded rather true This had been the opinion of the ward room for a good many months The worse jobs the ship was given the happier the ship became, and for some time it had been noticed that officers visiting the ward-room viewed us with a slightly alarmed air

It was difficult to explain the mental process of a young pilot who was returning on board in his aircraft from a duty trip to a station on the West Coast of Africa when he crashed on deck He climbed out of the remains of his aircraft and with a hangdog air and his hands behind him approached the captain, who was fuming with rage at the end of the flight deck Before the captain could let out his first bellow, the pilot produced a pineapple in each hand and said "I brought these for you, Sir" The war cry of the ship, which ward-room officers performed on suitable occasions, was a frequent cause of perturbation and the ammunition locker had often to be used for incarcerating young officers who became too disorientated In such surroundings the lunatics became indistinguishable from ourselves and I still remember the efficient RAMC officer's expression when he came on board to collect them and was told that though they were labelled 'Mentally Deranged" there was nothing the matter with them as far as we could see

* * *

It was obvious when we arrived at the hotel why the proprietor had been so gushing over the telephone, promising us Room —, apparently the best in the house The place was more than half empty We had been other extreme, the Rowett Institute tables (1938) give 12 6% and 11 7% for white flour and wholemeal which, if calculated for 75% and 85% extraction, would show a difference in the opposite direction of 0 3% All these values are obtained by interpolation A more satisfactory figure might be obtained from direct determinations on present-day samples of white flour and national wheatmeal Typical analyses carried out by Gordon Hay (1941) give values of 12 0–12 1% for white flour and 12 38–12 44% for national wheatmeal, a difference of 0 35–0 38% This difference is slightly higher than that recorded by Hamill for white flour with and without added bran (i e 0 29%) It thus appears that as I stated in my original paper, by adopting a difference of 0 5% both the Royal Society and I were unduly weighting the calculations against white flour, and that a figure of 0 35% would have been preferable



Graphs showing effect of extraction of wheat on the digestibility of the protein and energy of flour Reference to Bulletins will be found in Hamill's review (1911) for the remaining authorities see list of references at end of my paper

A similar conflict of views is apparent in considering the energy contents of the two types of bread Figures interpolated from the values given by McCance and Widdowson give 370 and 355 calories per 100 g for white flour and wheatmeal respectively The Rowett tables, on the other hand show a negligible difference between the two flours, while the mean of Hamill's figures shows a slight balance in favour of wheatmeal In these circumstances the adoption of the same value for both types of flour—364 calories per 100 g, the figure used by the Royal Society committee and myself—appears to be justified

FINAL BALANCE SHEET

The problem which both the Royal Society committee and I attempted to solve was whether the raising of the extraction level by 10% (e g, from 75% to 85%) would result in a net gain or loss of nutrients, taking into account not only the nutrients contained in the flour but also the value of the animal products produced from the available wheatfeed The Royal Society committee assumed that this wheatfeed would be converted into pig-meat for reasons stated in my earlier paper, I based my calculations on the assumption that it would be used for milk production. It appears from a recent statement made by the parliamentary secretary to the Ministry of Food (1942) that in the official view the loss of wheatfeed will result in a reduction in milk, eggs or meat For the purpose of calculation, and particularly in view of the facts noted in a current article (Wright 1942), it will be simplest to adhere to my original basis of calculation. Bacharach (1941) has pointed out that a balance sheet can be drawn up in two ways by assuming a constant weight of grain, or by assuming a constant level of flour consumption The former will give the *theoretical* gain or loss resulting from a change in the extraction level, the latter the *actual* loss of nutrients, taking into account the accompanying reduction in shipping tonnage

Using the new digestibility figures and incidentally adopting a correction suggested by Lester Smith (1941), the first method indicates that the raising of the extraction level should theoretically result in the loss of about 1000 tons of protein but the gain of sufficient energy to supply about 40 calories per head per day—though at the cost of many million gallons of milk The second method shows, however, that in actual practice the adoption of an 85% extraction level will result in a net annual loss of over 60,000 tons of protein as well as of over 1,600,000 million calories Krebs and Mellanby state that my original arguments against the raising of the extraction of wheat to 85% are not substantiated by their new data A re-examination of the balance sheet of nutrients in the light of the collected results reviewed in the present article does not support this rather sweeping assertion If, as is now advocated by Sir Ernest Graham Little (1942), the extraction rate were to be raised to 95–100% (that is, if the wholemeal loaf were to be compulsorily adopted) these already serious losses would be more than doubled

SUMMARY

The results recorded by Krebs and Mellanby for the digestibility of national wheatmeal are open to criticism

The collected results of earlier workers are reviewed, and the following mean values for protein digestibility adduced white flour 86%, national wheatmeal 81% For energy digestibility mean values are white flour 92%, national wheatmeal 88% For protein content white flour 12 00%, national wheatmeal 12 35% For energy content white flour and national wheatmeal, both 364 calories per 100 g

Judging from these figures, the annual losses of nutrients resulting from the adoption of the national wheatmeal loaf amount to over 60,000 tons of protein and over 1 600,000 million calories, adoption of the wholemeal loaf would more than double these losses

Royal College of Obstetricians and Gynæcologists—At a meeting of the council held on July 25, Sir William Fletcher Shaw was re elected president The following officers were also elected vice presidents, Prof William Gough and Prof C G Lowry, hon treasurer, Mr J P Hedley, hon secretary, Mr G F Gibberd hon librarian Wing Commander Frederick Roques, and hon curator of museum, Mr Aleck Bourne

Dr L C L Averill, New Zealand, was admitted in absentia to the fellowship The following were elected to the membership

Herbert Agar Muriel Boycott, J W D Buttery Marie H Calverley, T A Gillie, I M Jackson, W J McCord Mary K Lawlor, H M Wolff, and J F B Wyper

2 The induction with ethyl chloride is better carried out as the child lies asleep in bed before any moving is done.

3 At the first sign of restlessness after the operation, and in my experience this is more common than is implied by Gerrie and MacKenzie, an opiate should be given. 'Nepenthe' in doses of 1 min. per year of age is very efficient given hypodermically. This ensures quiet sleep for some hours and does not interfere with coughing or swallowing.

By these various means a guarantee in every case can be given to an anxious mother—rightly and reasonably anxious too—that her child will not know that he has had an anæsthetic or a tonsillectomy. There is no added risk in the anæsthetic provided that it is given carefully and with knowledge; but again, have we not now left behind us the days when "just a whiff of anything" was good enough for a child's tonsils?

A Military Hospital DOUGLAS BELFRAGE

USELESS AND DOUBTFUL DRUGS

SIR,—Dr Keele honestly displays his bias when he describes himself as a pharmacologist concerned largely with teaching students. It must be as annoying to such scientists to find practising physicians successfully using drugs which they have proved useless as it was, for example, to find people persistently using butter instead of margarine before the discovery of vitamins. Dr Keele seems to have forgotten that it is impossible to prove a negative and because he cannot in the laboratory find sound reasons for the use of a drug that is no sound reason for the exclusion of that drug from use: it is merely a sound reason for further research, preferably in the field of clinical medicine as well as in the laboratory.

The rôle of the pharmacologist is to discover the modus operandi of drugs rather than to decry the use of those whose mode of action he cannot discover. It is emphatically not his function to ask doctors to disbelieve their own experience because he has not himself made similar observations. The history of ergot and Barcroft's researches on fœtal respiration are both examples which justified the practice of the general practitioner and proved the dicta of the pharmacologist faulty. The teaching aim of the latter should be to instruct his students in technique and knowledge, and above all to cultivate in them that critical observation which will enable them later on to use drugs not because they are recommended in books but because they themselves have proved their worth in actual practice. When a method of research proves a placebo more powerful than drugs used with success by practitioners I think it is at least as reasonable to question the validity of the method as to accept its conclusions. Such researches are statistically interesting, but we do not yet know enough about any people or disease satisfactorily to apply statistical methods to them. I remember Sir Ronald Ross about 1913 glorying in a lecture that our knowledge of malaria had reached such a stage that we could now apply to it the methods of higher mathematics, but experience in the last war soon proved him wrong. Angina may be a striking event but its ætiology is not perfectly known and I have little doubt that if W. Evans's cases had all been under their own doctor's care they would have received individual treatment with better general results. Individuality in treatment is essential in medical practice, but it is necessarily ignored in medical textbooks which have to treat abstractions as if they were realities—i.e., discuss diseases instead of patients—and all too often hospital practice follows suit.

About 1915 I was as complete a therapeutic nihilist as anyone, but I have come to have a great respect for some of the older physicians like Yeo and Brunton who discoursed at length about prescriptions not only with an air of conviction but as the result of long experience and observation. The wise physician does not prescribe 'a small number of drugs with clearly demonstrated actions'; he studies his patient and knows that the balance of the prescription is of real importance, and not infrequently finds that an apparently small change in it produces greatly enhanced results. Clinically I am often surprised at the way in which patients detect quite small alterations in their medicines even though there has been no appreciable difference in taste, &c., and almost always their description of the changed effect is what one might expect. Can Dr Keele explain from his laboratory why small doses of diamorphine for example, make some people bad, and why even so innocuous a substance as peppermint will make some patients really ill? It is easy enough to call it idiosyncrasy or "psychological," but this is only ignorance under another name; and it is these psychological troubles which trouble many of our patients and which one psychological bottle of medicine will help to put right while another equally psychological will not.

The trouble with Dr Keele's teaching is probably that it is not based on experience in actual practice and this is largely true even of the hospital consultants. They are debarred from private practice and as a result never get the day-to-day, and sometimes hour-to-hour, experience of their patients which a doctor gets in general practice. Instead they surround themselves with the tremendously curative properties which—in our present civilisation—are attached to the ideas of specialist and hospital. They can put the patient to bed in standard conditions, where they do little but investigate him for a week or two, by which time he has adapted himself to these conditions and, unless he is suffering from the textbook diseases which Dr Keele wishes to treat with his few standard 'drugs with clearly demonstrated actions' he is sent out as cured or as having nothing discoverable wrong with him, only to relapse when he returns to his old conditions. While an inpatient he may have been treated with a bottle containing some simple drug or placebo and the budding medical student has been shown how little is the actual effect of such medication in producing the cure which, such as it is, mainly results from the regimen to which he has been subjected. Thus we breed a race of students ignorant of their own ignorance and anxious when they are qualified to carry on their work in conditions similar to those to which they are accustomed in clinics, and so escape the troubles which harry the general practitioner and make up much of the sickness in this country.

For in general practice our patients mostly cannot afford to stop work; they come to us not to be labelled but to be treated and if possible cured. Their deviation from normal may not be great, but it is irritating or worse and often elusive. In such conditions most of us do contrive, largely by our bottles of medicine, to give some relief and help the person back to health without the loss of time or the capital expenditure of consultant or hospital. Let the consultant criticise our methods by all means but let him remember that the problems and circumstances of our treatment are those that he himself has never actually encountered. The pharmacologist is still further removed from general practice. Perhaps we might even help to solve some of his problems if he did not so airily dismiss ours and pretend to a knowledge which is obviously incomplete. Doctors do not necessarily become fools when they become GPs, and some of us like to think we are doing our work as intelligently as we should if we had specialised in pharmacology.

This is not intended to deprecate the labours of pharmacologists or consultants for few can appreciate their help more than I do. It is merely to deplore that we work largely in different worlds.

Winsford, Cheshire W. N. LEAK

SIR,—There is something about drugs which leads to extremes in the attitude of those who have to deal with them. On the one hand are the manufacturers of proprietary medicines—"ethical" as well as "non-ethical"—who tend to use nothing but superlatives in describing their products. On the other are the critics, who launch out into sweeping generalisations against medicines, revealing a spirit no more scientific than the others. Dr Keele's letter of July 25 is an example of the latter class. How far is it correct to say that there is no sound empirical evidence that many drugs have any therapeutic value? What is sound empirical evidence? Dr Keele is apparently prepared to accept the evidence of one investigator, Dr Alstead, as sufficient to establish the inefficiency of ipecacuanha, iodides and bismuth oxycarbonate, but rejects the experience of *innumerable* practitioners. The folly of decrying such experience without the most thorough examination is well illustrated by the case of ext. ergotæ liq. of the BP rather nervous when our inquiries were received so warmly. This was by no means the first hotel in the neighbourhood we had tried and they had all been full. And after all it was our first holiday since the outbreak of war and was only to last four days, including a Saturday and Sunday. It would be tragic if it was ruined by uncomfortable quarters. The plunge, however, was duly taken and not regretted. The only other male inhabitants, apart from myself, were the proprietor (*a cast-off member of the aristocracy was our diagnosis*), a waiter in his 30's (*why wasn't he in the army?*) and a youth whose intelligence by no means matched his willingness. The visitors were the usual heterogeneous collection of females who seem to exist nowhere but in hotels, mostly rather antique, all very loquacious and none prepossessing.

Gastronomically we had little to complain of, but one piece of advice I would pass on to anyone who has not yet sampled hotel life in war-time: take your own marmalade. It was only provided on alternate mornings. Otherwise we were well cared for—eggs twice for breakfast, meat or fish for both lunch and dinner each day, though possibly the helpings were on the small side. Of beer and gin there seemed to be no scarcity; at least there was ample for my moderate purse. A large notice in the bar announced "No Doubles," but that did not prevent the platinum blonde who arrived for dinner one evening getting two "double gins" as an aperitif. Newspapers were unobtainable and as the only wireless set was invariably surrounded by a circle of chattering females at 9 o'clock we were deprived of the doubtful pleasure of hearing the news. For some odd reason there seemed to be no scarcity of Sunday newspapers; the waiter astonished us at Sunday breakfast by coming to ask which one we would prefer.

So passed the four days in arcadian calm—breakfast, a leisurely walk, lunch, siesta, tea, another stroll, drinks, dinner, bed. The only evidence of war was an occasional military lorry and a bar-load of Canadian soldiers in the evening. There was scarcely a car on the road, and even pedestrians were few and far between apart from "locals." And these Surrey lanes are lovely—a good second to the Cornish ones. The only depressing sight was the derelict appearance of so many of the lovely houses; not the stately mansions—these we avoided—but the smaller houses built and occupied by the successful professional, military or business man. They were still occupied but everywhere was evidence of neglect; paint was obviously considered a luxury, the flower gardens were overgrown, the hedgerows were uncut. Here was the impact of the war on this lovely countryside.

Yes, the hotel served our purpose well. It provided the panacea for all ills these days—a brief escape from the realities of the day. But (mention it not in Gath!) the main effect of my holiday was to make me thoroughly discontented for the next few weeks. The almost unbroken work habit of three years had been rudely shattered. When *would* the war end?

* * *

A dozen times this year I have asked gardeners in action what they are thinking about, and I find their minds are projected three or four months ahead. That a man who is planting out lettuces should see and gloat over the prospect of their succulent maturity is not surprising, but that one working in the glory that is June should be filled with autumnal longings, or that he who might be enjoying the consummation of harvest should find the prospect of bleak December ploughland compellingly attractive, stirs thought. It is easy to see how this trick of prevision would quickly act selectively, benefiting and preserving him who stored, and staying the nomad. When some future Darwin comes to write the natural history of man, when the psychologists have waded out of the Freudian swamp, have climbed a little and distanced their horizon, then it may be found that this ability to see in pictures the scene some moons ahead, having divided birds into migratory and resident, having made hibernation in mammals possible, has played an important part in man's evolving. It is the essence of good husbandry and business, of strategy and the lust for planning; it is the cause of divine discontent with the present, and in the musically and aerially minded it has defined the life hereafter; but it has undoubtedly misled many into thinking they can spot the winner of the 2.30.

Letters to the Editor

WHAT IS GANGRENE?

SIR,—In a recent pathology examination the answer to a question on gangrene puzzled my coexaminer and me by stating, almost consistently, that gangrene is necrosis plus putrefaction. Each of us doubted this definition, having always held that bacteria play no constant part in the causation of the dry variety. However, we found that the answers reproduced what the students had been taught and that this teaching appears in many modern textbooks—e.g., Muir, Boyd and Karsner. Other books (e.g., MacCallum, Green and Aschoff) do not consider the presence of putrefactive bacteria essential to gangrene as a whole, though mentioning it, of course, in connexion with the moist variety. Kaufmann (1929) holds necrosis and gangrene to be interchangeable terms and writes: "The entrance of organisms of decomposition produces softening, that is moist gangrene."

A short search for evidence of putrefactive bacteria in dry gangrene was fruitless, and discussion in a group of four professors of pathology or bacteriology and a number of other experts betrayed a striking absence of corroboration. I came to the provisional conclusion that recent pathological writers have been over anxious to find a scientific way of distinguishing gangrene from necrosis, and to this illicit and superfluous end have dragged in putrefaction. Superfluous because gangrene lays no claim to be a precise scientific term, being far more a clinical or at most a morbid-anatomical conception, and so it does not in the least compete with necrosis. Gangrene, in my view, is a gross manifestation of necrosis with or without subsequent putrefaction. Surgical text-books (e.g., Illingworth) bear this out by defining gangrene simply as massive necrosis. On the other hand, there may be solid evidence that even in dry gangrene putrefactive bacteria are always present. Can any of your readers tell me where such evidence is to be found? If not, writers of pathological textbooks will perhaps make the necessary correction in their next editions.

Oxford. A. D. GARDNER.

CONSIDERATE TONSILLECTOMY

SIR,—It is encouraging to learn from Mr. Gerrie and Dr. Ross Mackenzie in your issue of June 27 that one more hospital has turned its back upon the barbarities of outpatient tonsillectomy in children, though one had supposed that a procedure so characteristic of the philosophy of blood and iron was already a thing of the past in this country.

It should, of course, be axiomatic that any form of surgical operation upon a child should be done without the child's knowledge, in so far as prevailing conditions permit, and that to this end basal narcosis should be as nearly as possible one hundred per cent effective. For large numbers of children undergoing tonsillectomy in hospital the scheme described by Gerrie and Mackenzie is admirable, and I endorse their opinion that pentobarbital ('Nembutal') by the mouth is the best drug available for the basal narcosis. In the absence of the elixir, the powdered drug—not, of course, the capsule—is always taken without difficulty in honey, malt, or other such medium. By contrast, anybody who has often attempted it must know that rectal administrations of paraldehyde or bromethol frequently cause more psychic trauma—or, in plain language, no end of a rumpus—in a nervous child than does the clever administration of an anæsthetic.

The secrets of success with oral pentobarbital are organisation and taking trouble, and in this connexion I would add the following points to the Aberdeen scheme:

1. In non-hospital practice, either in a private hospital wing or in the child's own home—the latter in my experience the best place for tonsillectomy—much is to be gained by operating in the evening. The child goes to bed at the usual time, and with his invariable ritual except for the pleasant surprise of a teaspoonful of honey or what not. He goes to sleep without question, and wakes in the morning with a sore throat, but otherwise oblivious that anything unusual has occurred in his familiar world. To expect a boisterous child to settle down to sleep at 9 A.M., though perhaps inevitable in hospital practice, is to give the game away at the first move.

decry our country, our mode of living and our institutions and it was inevitable that sooner or later our profession would become the target I submit we owe no apology to anyone, and we can look back on the past 20-odd years with the greatest satisfaction at the progress that has been made in giving better service to the public By all means let the process of improvement go on, but what we need now more than ever before, is progress based on stability Let us build on what we already have If radical changes in medicine are the necessity that some people think they are then in all fairness let it be done at a time after the war when those now on service will have an opportunity of putting their views forward, and when the profession as a whole will have the help and advice of those who are now fully *engaged in trying to preserve a future for all of us*

Cheam, Surrey C C BROWN

PERMISSIBLE ON OCCASION

SIR —In his eloquent speech in the House of Commons on July 22 to which Medicus MP gave proper attention in your last issue the Minister of Labour preached the *public health gospel as a major help to efficiency and so* to increased output I sought but missed the opportunity to point out that the demand for increased output may be carried to excess Competition has its dangers A stand must be made against the appeal in the name of patriotism, for long hours no holidays Sunday labour Like alcohol these excesses may be permissible on occasion But they are boomerangs, very soon they diminish efficiency and output They are responsible for much reasonable absenteeism There is no excuse for their continued practice The Industrial Health Research Board has shown the limits and conditions of endurance , but its reports remain unread by those who are most concerned Managements, in their own interest should be required to know the Research Board's specific findings on stated experience

House of Commons FRANCIS FREMANTLE

TREATMENT OF THE CRUSH SYNDROME

SIR,—Mr Patey and Dr Robertson's refutation of a toxæmia as the cause of the "crush syndrome" is a blow at a cherished conception but I am with them in their heresy Here are some of my reasons

1 The occurrence of the syndrome when the main vessels of the limb, above or at the level of the injury were destroyed at the time of injury, which puts out of court, entirely or mostly, the absorption of autolytic products

2 The absence of the syndrome in cases of ischæmic myositis, due to bad splinting or tying a main vessel, leading to Volkmann's contracture, and its absence in street accidents before it became the practice to give massive transfusions

3 The absence of a time relationship between the duration of burial and the development of grave renal failure in air-raid casualties "The average period of burial or crushing has been about 8 hours, but we have recently seen a case in which the patient was trapped for only 45 minutes at most " (Belsey, R H R *Proc R Soc Med* 1941, 35, 329) A man of 24 developed renal failure after having been "pinned for five minutes beneath an overturned Bren gun carrier" (Williamson, J C F L and Janes, J M *Ibid*, p 336) The same happened to a man who was ' extricated almost immediately " after a road accident (Graham, W H *Ibid*, p 335) Of the cases published by the Medical Research Council sub committee (*Brit med J* 1941, i, 449) the average duration of burial of the 5 patients who recovered was nearly twice as long as that of the 5 who died Even micro organisms require a latent period, but reflex actions appear immediately To such reflex action I assign the renal disability, evident on admission in all or in the great majority of air-raid casualties who subsequently develop grave renal failure If a latent period for this does exist it is related to the time of admission and the giving of massive or even not massive transfusions To suppose the renal disability starts from the time of release is to suppose that during the whole period of compression the blood-flow through the limb—the return of blood to the systemic circulation absorption from the dying *muscles—is stopped*

I cannot accept Patey and Robertson s alternative They impute the crush syndrome to the ' loss of blood *constituents into the injured limb* " , it thus becomes a deficiency disease Truly, shock is a deficiency disease, but the deficiency consists not in a *loss* of particular chemical constituents from the blood it is of a physical character The occurrence of œdema in an injured limb, associated with the accession of blood to the skin by the application of heat in people who have been exposed on the battle-field or in bombed houses and have become dehydrated explains the shock noted in many cases only after treatment—the application of heat—has begun The limitation of œdema by bandaging, or the attractive other means advocated by Patey and Robertson as a means of preventing shock, is all to the good—it prevents the administration of a massive transfusion ' But whether it prevents renal failure is another question

In no 7 of the MRC cases polyuria appeared with œdema, or close on its heels A man of 34 buried for 22 hours was admitted ' cheerful " with no shock, and shock did not develop Oliguria was present from the start on the second day the output of urine was 300 c cm , on the third 420 c cm , on the fourth 420 c cm The note for the fourth day adds ' Both legs swelling rapidly and becoming œdematous next day the output of urine was 2190 c cm What other explanation of this can there be but that the vascular system inundation of which had been attempted by pushing fluids but had been largely frustrated by vomiting was decompressed by the rapid pouring out of fluid from the blood-stream into the legs relieving turgescence of the kidneys ? In the same way in a case reported by Ruscoe Clarke (*Proc R Soc Med* 1941 35 339) "Prior to operation"—an amputation—"marked oliguria accompanied a normal blood-pressure . During and immediately after the operation a marked drop in blood-pressure was accompanied by polyuria ' Is it not curious that a marked fall of blood-pressure should be accompanied by polyuria ? Patey and Robertson state that strong experimental support for their view has been furnished recently I have not read the paper, but laboratory experiments cannot blot out the evidence which is afforded by clinical experience on man and appears in reports often in laconic remarks

Essential conditions are sometimes missed, both in the laboratory and at the bedside, and the conclusions in consequence are misleading Patey and Robertson's argument is an example They say that positive intermittent pressure applied to an injured limb may prevent renal failure and in their paper (*Lancet* 1941 i, 780) they described a case (their case 3) But in their recent letter they omit to mention that the fluid intake in this case during the first 24 hours was only 1650 c cm , and on the second day only 1410 c cm The intake was deliberately restricted it appeared to them "that large intravenous injections of plasma or crystalloids before or during the shock phase would tend primarily to increase the loss of blood constituents into the damaged limb with subsequent promotion of traumatic œdema ' That large intravenous injection of plasma by inducing a turgescence can have any pathological effect on the kidney, or that the fluid intake of 7440 c cm (3000 c cm by vein) during the first 24 hours in their case 1, in which compression treatment was not tried and the patient died from renal failure caused or contributed to the renal failure was not considered Nor did they discuss whether the restriction of fluid intake played any part in preventing renal failure in their case 3

Two other points are passed by One is whether heat was applied to the patients In view of the case recorded by Richard Bright in 1827 (Osman A A Original papers of Richard Bright on renal disease London 1937 Case 4), that of a man who being very hot by carrying a great weight ' drank cold beer and lay on damp grass and developed renal failure and died, the state of the skin arterioles seems of consequence The other point is the position of the patient's body This is of the greatest importance in my view the Trendelenburg position is the sheet anchor in the prevention and treatment of shock When renal *failure has* developed, the best posture is the semi-sitting with the feet somewhat raised Renal decapsulation is useless unless done early *in one of two* cases published by Clifford White (*Proc R Soc Med* 1919, 12, 28) the operation was followed by the passage of a large *number* of casts, absent before—the uriniferous tubules (the loops of Henle) could distend

In a case I saw 10 years ago (Hayes, D S and Parmore, R H *Lancet*, 1935 ii, 554) anuria, which complicated an abdominal condition, was treated by two

1914 This preparation was ridiculed by pharmacologists as worthless in spite of the strongest clinical evidence, only eventually to be shown to contain an active principle which fully justified the claims made for it Alstead has certainly demonstrated to his own satisfaction that ipecacuanha and iodides are of little use in the treatment of chronic bronchitis, but his work has not been generally accepted Furthermore, it may be true that bismuth oxycarbonate does not possess the property commonly assigned to it, but the way to settle the issue both in this case and in the others Dr Keele is concerned about is not to "wonder"—as he does—how many drugs would fail to stand up to adequately controlled therapeutic tests but for him and his fellow pharmacologists to make such tests This applies in particular to the few examples he quotes from the NWF If there is any doubt about the value of ammon carb to diminish the unpleasant taste of cascara why not try it out ? Even if creosote is not excreted in the sputum after oral administration it may still have a therapeutic effect Search of the literature may give information or investigations should be made I am surprised to find that Dr Keele could be in any doubt about the use of mist strych et ferri It surely is a tonic The codeine in tab codeinæ co has an analgesic effect , to what extent it is responsible for the total analgesic effect is a problem for pharmacologists I am wholeheartedly in agreement that the formulary should include only drugs that give convincing positive evidence of their worthiness, but any drug that gives therapeutic results should qualify for inclusion I fail to see any distinction between pharmacological and psychological action a psychological action clearly is a pharmacological action It is the aim of such a formulary to include prescriptions that are needed, using the limited range of drugs available It is up to the pharmacologists to teach clinical students what they believe to be rational therapy, and I trust they are not forced to discuss and recommend the use of drugs against their better judgment

Pinner H W TOMSKI

THE MILK FACTOR IN CANCER

SIR,—The annotation on Bittner and his forerunners in your issue of July 25 prompts me to call attention to the fact that the milk factor in the transmission of disease to sucklings has exercised the minds of philosophers from very early times The matter is discussed in Burton's "Anatomy of Melancholy," first published in 1621 The discussion naturally includes statements and records which might not bear critical investigation, but the following extracts are interesting and significant in view of the present-day scientific proof of a milk factor in the transmission of cancer in mice

> Aulus Gellius (a second century Latin author) brings in Phavorinus, that eloquent philosopher, proving this at large, "that there is the same virtue and property in the milk as in the seed, and not in man alone, but in all other creatures " Giraldus (the literary name of the twelfth century historian and ecclesiastic, Girald de Barri) came to the conclusion "that men and beasts participate of her nature and conditions by whose milk they are fed "

Portland Place, W 1 ALFRED WEBB-JOHNSON

DIFFERENTIAL DIAGNOSIS OF DYSPEPSIA

SIR,—Sir Arthur Hurst and Major Venables misquote us in saying that we regard gastritis as the cause of severe symptoms Certainly our conception of this condition appears to be different from theirs, but we went so far as to say that the symptoms were not so severe as those of peptic ulcer although, because of the lack of remissions and the intolerance of dietetic indiscretion, they tend to assume a greater significance We maintain that symptoms in any organic disease can be materially affected by psychotherapy and suggestion, but Hurst's success in the symptomatic relief of his gastritis patients is no proof that the symptoms were those of an anxiety state

With regard to other therapy, we have not been impressed by the results of simple diet and gastric lavage, having obtained maximal symptomatic and gastroscopic improvement only after adherence to the strictest dietetic regime with hourly feeding over a period of several weeks We have been through our cases again and find that the duration of symptoms after the commencement of strict treatment is just twice as long for gastritis as for uncomplicated peptic ulcer Cases of gastritis which were discharged before symptomatic relief was obtained are excluded from this estimate , if they could have been included, the comparison would have been more striking At least half the soldiers with chronic bronchitis state that they have no cough, but on close questioning admit to a cough which they consider normal Similarly many men with gastritis regard their "indigestion" as normal , the same is true even of some men with ulcer In our opinion gastritis is paralleled rather by chronic bronchitis than by effort syndrone and although a proportion of men with gastritis are symptomless because of their extraverted mentality, the symptoms complained of by the more introverted type are, nevertheless, primarily caused by their gastritis

The radiological diagnosis of duodenitis, using Berg's technique, is founded on much more definite changes than is the case with gastritis However, the crux of Sir Arthur Hurst's criticism is the absence of pathological confirmation , *in fact many workers, including* Kirklin, Nagel, Rivers, MacCarty and Wellbrook (to quote only references in English) have proved the diagnosis pathologically and have shown that superficial erosions and even massive hæmorrhages occur in duodenitis In our series, for every five correct clinical diagnoses of duodenal ulcer, one was diagnosed as duodenitis yet, of the duodenitis cases, for every one diagnosed wrongly as ulcer, four were clinically diagnosed correctly We consider this degree of clinical accuracy significant

An EMS Hospital F R BERRIDGE

DOSAGE OF LOCAL ANÆSTHETICS

SIR,—The most instructive article by Dr Organe in your issue of July 11 prompts me to plead that drugs used for regional anæsthesia should be kept in powder form, contained in sterile ampoules The powder (which has been accurately weighed by the maker) when dissolved in the appropriate amount of sterile normal saline (or CSF for subarachnoid block) gives a fresh, active anæsthetic solution of known strength and uniform reliability Ready-made solutions tend to deteriorate on keeping, or may undergo a change in concentration, such as Dr Organe describes in his first case where evaporation had increased the strength of the solution The anæsthetist can never be sure how efficiently a ready made solution has been prepared, and it is he who i responsible should any ill effects occur I have never regretted adopting the method of preparing solutions which Labat many years ago advocated in his cla ic work

Twickenham NORMAN R JAME

REACTIONS TO THE REPORT

SIR,—The demands on the personnel of our profession are more severe now than ever before and may well be harsher still Many of us are hard put to it to keep things going while our colleagues are away Under these circumstances, it is fantastic that members of the profession, some of whom were not specifically elected for the purpose, should be spending part of their time devising a scheme for a post-war world that no man can even visualise We are an amazing people Why all this urgency to produce a plan ? Is it as many think because there is a certain group in medicine determined to introduce some form of state medical service at the earliest possible moment ?

The majority scheme put forward would introduce so many changes in medical practice, as we know it at present, that it is frankly revolutionary Revolution of any kind are not popular in this country, especially when they are being pressed by the few upon the many It is wrong to state, as a correspondent does in your issue of July 4, that "The majority of the public is only too aware of the many shortcomings of the medical services available to it" This is merely an assertion with nothing to support it He accuses the profession of having "failed to give an intelligent lead to the public," and concludes by saying "This is our moment , let us have vision beyond tomorrow and build worthily for the future" That is a sad mixture of defeatism, emotionalism, and inaccuracy

During the last few years it has been a favourite hobby of some, especially our left-win tellectuals, to

Lord Dawson said that although we were rightly concerned with the increase of tuberculosis in this war, it was important to keep our sense of proportion The total increase in mortality from tuberculosis since the war amounted to 13% in Great Britain A more anxious feature was the selective character of the infection among different classes As in the last war, there was a tendency for an increase of infection among young women, but in this war there had been a novelty in the extension of the infection among young children, particularly in the incidence of tuberculous meningitis, from which there had been increased mortality of 50% But on the whole he believed tuberculosis was under control, and though 13% was a considerable figure there was no sign so far of the disease running away with us Even in the peak year of 1938 there were nearly 250,000 people being looked after in tuberculosis dispensaries Tuberculosis was a germ disease which did not come in waves It was always with us, and its root was in almost every country It was at once curable and at the same time very destructive It could destroy life in a few weeks, but most cases were so mild that the patients were not even aware that they had been attacked In a country like ours, where a large proportion of the cattle were tuberculous, it would be wise to pasteurise our milk The medical profession had been pleading for years with successive Governments to make pasteurisation compulsory But prewar Governments had been stiff-necked and pasteurisation was patchy—not so good in the country as in London and some of the larger centres Lord Dawson suggested that the increase in tuberculosis in children might be partly accounted for by the fact that owing to evacuation so many had consumed raw instead of pasteurised milk Lung tubercle was caused by contact with the expectoration of an established case, and under the overcrowded conditions of war the opportunities of contracting tubercle must be greater than in peace The difficulty of diagnosis of patients with vague symptoms was a matter for watchfulness Mass radiography was making progress, and we were not dependent solely on the United States There were machines in this country which had been standardised according to an agreed pattern, and which would now be turned out in increasing numbers In skilled hands 3000 examinations a week were possible He thought we could do far better in this country by persuasion than by compulsion, that mass radiography would be received with increasing favour as people got to understand it But it must grow *into* our system of medicine discreetly and to dispatch machines all over the country without proper teams to work them would make a bad beginning Lord Dawson was doubtful about the education of the public by cinema it was difficult to give information about health without causing alarm Workers might swing from indifference to over-anxiety, and he himself almost preferred indifference The rehabilitation of the tuberculous patient had not been sufficiently provided for in the past but he believed that the Ministry proposed to consider seriously the maintenance and subsidising of tuberculous patients from the time they leave the sanatorium till they return to full employment In England the care of the tuberculous was primarily the duty of the local authority, but Lord Dawson thought that the emergency medical service might appropriately provide on a larger scale for tuberculous people If it were made clear that there was no more risk of a nurse catching disease in a sanatorium than in an ordinary hospital—in fact rather less, if anything—and if in some way the tuberculous patient could be made part of a nurse's duties—she might for example be seconded from medical or surgical wards to tuberculosis wards—he believed that the nursing difficulty could to a large extent be overcome But he was sure that any attempt to compel nurses to take up any particular phase of nursing would end in failure

Lord Snell replying, said that we must remember that the shortage of nurses and domestics is only one phase of the Government's problem to make the *best use of* woman-power Though the position was unsatisfactory it is slightly better than a year ago Over 90,000 nurses were now working in civilian hospitals—8000 more than a year ago It was estimated that another 12,000 nurses were required There were 2000 nurses employed at sanatoria and another 600 were required and a further 600 for tuberculosis beds in other hospitals He admitted that the percentage deficiency was therefore higher in sanatoria than in general hospitals and that experience showed that tuberculosis nursing was not so attractive as other services The Government was reluctant to adopt compulsion for nurses, but Lord Snell said that in the last resort they might have to consider a wider exercise of powers of direction The decision not to allocate nursing auxiliaries under 21 years of age to sanatoria even if they volunteered had been taken by the Minister on medical advice that this age-group might be particularly liable to infection A proposal had been put before the Standing Advisory Committee on Tuberculosis by one of its own members that the Ministry should be asked to withdraw the embargo The committee felt unable to agree to this but had suggested young nurses might be allowed to serve in institutions dealing with non-pulmonary tuberculosis This recommendation was adopted in Circular 2526 The Government had lately reconsidered the matter and they felt that perhaps in present circumstances nursing auxiliaries under 21 might be allowed to serve in sanatoria if they volunteered provided that the fullest precautions were observed in looking after their health

Summing up, he said we must not forget the improvement in the general health of the community which someone had impishly suggested might be due to the call-up of 10 000 doctors but Lord Snell felt that we should defer criticism of the doctor until he had been provided with the social conditions to make his work effective The Minister of Health shared in the anxiety felt at the new encroachment of tuberculosis and he would continue to take every means open to him to get staff deficiencies remedied and the needs of an essential service fully met

QUESTION TIME

Quality of the National Loaf

Sir E Graham Little asked the Parliamentary Secretary to the Ministry of Food whether his attention had been drawn to the experiments conducted by three scientists of the Children's Nutrition Council of Cambridge, in which they examined 17 samples of national bread obtained from widely different sources, in 7 of which the Ministry's specification with regard to the maximum fibre content was not complied with.—Mr. W Mabane replied These experiments were made on flours milled before national flour became compulsory and confirm to a large extent the results of the larger survey carried out on similar flours by the Research Association of British Flour Millers on behalf of my department The difficulties connected with the standardisation of so small a part of a miller's production were removed when national flour became compulsory and this report recognises the improved quality of national flour since its compulsory introduction.

In reply to a further question Mr Mabane said that in the two weeks ending on July 11, the average production of wheat-germ by controlled millers was at the rate of 19 tons per week

Sale of Tuberculin-tested Cows

Mr David Adams asked the Minister of Agriculture whether he was aware that it is common for cows which react to test for tuberculosis to be sent to market and sold as healthy cows, thereby spreading the disease, and whether prompt steps would be taken to prevent this practice —Mr R S Hudson replied The sale of cows reacting to the tuberculin test is not, on that account, restricted In view of the very much larger number of untested cattle which, if tested, would react, no such restriction would serve any useful purposes —Mr Adams Is the Minister aware that many cows seriously affected with tuberculosis are permitted to be put on the market and disposed as healthy cows? Is that satisfactory? Mr Hudson That is merely repeating the question which I have answered

Scientific Coöperation with Russia

Mr R K Law, in answer to a question, stated that some fifty inquiries from British men of science and scientific *institutions* have already been forwarded through the British Council to Soviet scientific institutions in the last eight months Exchange of information has been encouraged by the formation by the council and Ministry of Information of a joint advisory committee of British men of science whose chairman is Sir John Russell of the Ministry, and vice-chairman and secretary officials of the council injections of tropacocaine into the spinal canal, the idea was to relax the abdominal muscles and cause a fall of blood-pressure As in Ruscoe Clarke's experience, the renal state was rapidly righted The same result one may reasonably suppose would happen in cases of renal failure developing in air-raid casualties The result in my case was magical, and when the man was seen last year he was still fit

Rugby R H PARAMORE

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS M P

"FEW things have such an important bearing on morale as food," said Mr Mabane, who has taken over the duties of Parliamentary secretary to the Ministry of Food from Major Lloyd George, and Mr Hudson, as Minister of Agriculture was able to give such a good report of production that our food is assured The whole of Mr Hudson's speech, which took about half an hour, was packed with facts and straight-punching statements But he made a second speech of five words only when Mr Owen Evans of Cardigan said that we were producing more than half the food-supplies of the country in the interjection "It is nearly two-thirds" With our present food production, our existing stores of imported foods, our reserves of meat on the hoof and the increase of agriculturally self-sufficient people to over two million we could live well, but with a reduced meat ration, if we imported practically nothing at all until next harvest This change from an agriculture dependent on imported feeding-stuffs for its sheep cattle and horses, and a human population dependent for a very large part of its bread, butter, eggs, meat and fruit on imports to what is a self-sufficient agriculture is a revolution which deserves even higher praise than the House gave in the debate

Well might Colonel Walter Elliot, himself minister of agriculture in the past, say that the Minister's statement pointed out "the shape of things to come" The Ministry of Food should continue after the war and food subsidy should be an integral part of our agricultural administration Food subsidy at present, Mr George Barnes told us, costs 125 millions a year But private out-of-date marketing arrangements cost us 1500 millions a year, according to Mr Evelyn Walkden, who has made himself an authority on this subject The prospect opens up of nationalised food marketing with continuance of food subsidies to agriculture still further reducing the cost of food And in this war food is cheaper than in the war of 1914–18

Mr Hudson told us how these results had been obtained on the one hand by a scientific direction of agriculture, on the other by a complete state control through the county agricultural committees of the use of land This year there is to be in England and Wales an increase of tillage by 500,000 acres, mostly wheat, so that by next year we shall have 600,000 more acres under wheat But with this there is a great increase in milk production and every farmer is asked to keep the maximum head of stock he can feed with his own resources There is complete state control and the power of direction of farming to any extent required, but Mr Hudson's policy is to work by getting the active cooperation and interest of the farmers, and he succeeds by making personal visits to all parts of the country, and by insisting on the recognition of the individuality of the farm, even of the field, and by decentralisation of administration Perhaps the most striking aspect of Mr Hudson's policy is his reliance upon and usage of scientific research The Agricultural Research Council is the active instrument employed "to obtain the maximum possible knowledge and relate it to the needs of agriculture" The Agricultural Improvement Council, set up last year, has the duty to "get the results of research adopted and utilised more quickly in farming practice" In order to avoid overlapping of these two bodies the Minister has appointed a certain number of members of each body to be members of the other And in addition there are frequent meetings of the two secretariats The work of the Agricultural Improvement Council is decentralised, to the limit, practical demonstrations are arranged "not merely on two or three farms in a county belonging to a farm institute but on many average farms, right down to farms in individual parishes" The results of the first year's experience of the working of this organisation of science and applied science is the assurance of the marriage of research and practice "We are today," Mr Hudson claimed "making the maximum possible use of all the scientific agricultural knowledge that we can possibly lay our hands on" The Minister, however, is no mere utilitarian and he took pride not only in the increase of food production but in that mixed farming which, with its waving fields of crops of infinitely great variety of colour, had made the countryside so beautiful

The debate was certainly on a high level but did not come up to the imaginative and farseeing level of the Minister's statement Colonel Elliot protested against any return to the "wheat mining and wheat quarrying" that has gone on in Canada and the U S A and other countries of the New World and which in the name of cheap food has destroyed English agriculture and produced the dust bowl of the Ohio valley Flight Lieutenant Boothby tried to sell the oats of Aberdeen to the Ministry of Food—apparently quite willing buyers Some members talked of the waste of potatoes—that is the part of the insurance reserve not used this year—and Mr Mabane was able to say that this amounted to only 2 days' supply for human consumption A suggestion was also made about incorporating oats in bread There are possibilities of this, but they are limited, and if we are to add rye and potatoes (we did use potatoes in the last war) bread will be a very motley compound

With the minds of all members gravely concerned about the war situation in Russia and the possibility of relief to this threat to the Allied lines by opening a second front, this food debate was a relief In one vital and fundamental matter—namely, food-supply—a second front based on these islands, and the production front in these islands, is secure

FROM THE PRESS GALLERY

Tuberculosis in War-time

IN the House of Lords on July 28 Lord DAVIES drew attention to the failure of the Ministry of Health to deal with the staffing requirements of institutions for the treatment of tuberculosis Since the war there had fortunately been no great increase in the number of cases but the number of deaths instead of continuing to fall had increased from 26,176 in 1938 to 28,669 in 1941 There were unfortunately many people awaiting institutional treatment—1507 in England, 400 in Wales and 652 in Scotland This figure did not include ex-Service patients and in Wales there were a further 130 ex-Service men on the waiting-list He appealed to the Ministry to increase the facilities for these people to use empty beds in the emergency hospitals and, above all, to help institutions to keep open the beds they had He thought the Government should withdraw Circular 2340, which, he alleged, aggravated the shortage of nurses It gave women the choice of the type of institution in which they would serve and by refusing to allow girls of under 21 to volunteer for service in tuberculosis hospitals suggested that the risk of infection was greater there than in general hospitals When men were being sent to fight Lord Davies thought women should be sent where their services were most needed and he asked that the Ministry of Labour should include nurses and hospital domestic staffs in the categories of essential or vital war work He also urged that the proceedings of the Rushcliffe Committee should be expedited, and that the manufacture of instruments for mass radiology should be speeded-up

Lord CORK and ORRERY suggested that it would ease the situation if the General Nursing Council would introduce three months in a sanatorium into the training of nurses and this would be an advantage educationally Lord HUNTINGDON understood that 20% of the country's general practitioners had been called up by January, 1941, and since then another 1400 had been taken Could army doctors not help overworked general practitioners? He pleaded for the compilation of a tuberculosis register by the General Nursing Council, similar to those for fever and mental nurses

FRACTURES OF THE OS CALCIS

ORTHOPÆDIC SURGEON TO THE MIDDLESEX HOSPITAL

THE results of the treatment of crush fractures of the os calcis are rotten. They bear no relation to the accuracy with which the fractures are reduced With few exceptions the result of Böhler's method of reduction and fixation in plaster is a permanently stiff and painful foot on which no man can do a day's work or indulge in any form of sport or exercise The reason for this is clear Any severe injury of a foot, even a bad sprain, which is immobilised in plaster for four months will result in a stiff and painful foot ; the movements of inversion and eversion will be limited or abolished, and, since these movements are required for normal use of the foot, walking will be difficult and painful especially on uneven ground And when to this is added the trauma of a fracture involving the subastragaloid joint, traumatic arthritis follows and completes the crippling of the patient. So it often happens that after a year or more of continuous disability the patient is advised to have a subastragaloid arthrodesis

The immediate results of treatment by rest in bed with massage and movements from the start are very much better than those of reduction and plaster. In many cases fairly good subastragaloid movements are preserved and the patient is able to walk with comparatively little discomfort But sooner or later traumatic arthritis follows and the foot becomes stiff and painful

The results of subastragaloid arthrodesis for fractures of the os calcis are often unsatisfactory, because (1) the operation is incomplete and the mediotarsal joints remain stiff and painful ; (2) the foot is flat and ill-adapted for heel and toe walking ; (3) after many months the patient has become accustomed to a stiff and painful foot

It would seem that the best result that can be obtained from a fracture of the os calcis involving the subastragaloid joint is a completely stiff, but painless, foot of a good shape and with free movements at the ankle-joint, and I suggest that a complete triple arthrodesis should be done at once as a primary measure in such cases This operation gives good functional results in paralytic, congenital and other deformities of the foot, and there is no obvious reason why it should not give equally good results in fractures of the os calcis

In performing triple arthrodesis for recent fracture of the os calcis a slight modification of the usual procedure will be found useful In these cases it is difficult to dislocate the foot inwards at the subastragaloid joint, because the bone is apt to come to pieces during the manipulation A short longitudinal incision is therefore made first on the inner side of the foot over the scaphoid Through this incision the scaphoid is excised and the cartilage is removed from the head of the astragalus and the bases of the cuneiform bones This incision is then closed The usual incision is then made on the outer side of the foot, and the calcaneocuboid joint is at once excised The subastragaloid joint is now opened and dislocation of the os calcis is easy, because the bone is free from its anterior connexions

The articular surfaces are removed piecemeal and the fragments of the os calcis are manipulated so as to restore the normal prominence of the heel Finally the foot is displaced backwards and the operation is completed in the usual way. The foot is kept in plaster for four months, during which time the patient may get about on crutches but is not allowed to put weight on the limb

As yet only two of our cases have completed the treatment and are walking without plaster, but both of these have active painless feet and they compare most favourably with any cases that I have seen treated by other methods

---

INCIDENCE OF NEUROSIS IN ENGLAND UNDER WAR CONDITIONS*

AUBREY LEWIS, M D ADELAIDE, F R.C P
CLINICAL DIRECTOR AND LECTURER IN PSYCHIATRY TO THE MAUDSLEY HOSPITAL

IT is not easy to decide whether a mental disturbance—neurotic or otherwise—is directly attributable to war conditions, and particularly to air-raids It is therefore more informative to find out whether there is more, or less, neurosis altogether since the war, or since the intensive air-raids, than to count up the cases that seem to have been caused by the war The latter criterion, however, is sometimes used If the number of civilian patients admitted to special EMS neurosis units all over the country be taken as the measure then there were not more than 300 such cases in the nine months, October, 1940, to June, 1941 The total number admitted in England and Wales during that period was 291, of whom 42 were admitted in May, 1941, and 94 in June, 1941. The apparent increase in the summer of 1941 was due to an influx of persons referred to the neurosis centres not necessarily because they needed inpatient treatment but in accordance with a newly instituted policy whereby all persons receiving an injury allowance for "shock" or similar neurotic reactions were required to enter hospital for an expert opinion on the cause of their illness, and for treatment ; many of the latest admissions represented cases of unnecessarily long-continued payments

The Ministry of Pensions has to deal with "shock originating from direct exposure to bomb explosion or blast"—a loose term covering neurotic reactions, as well as suspected but not verified physical injury from blast, and states of fatigue and exhaustion. In the first few months of the intensive raids from September, 1940, about 100 people a night were admitted to first-aid posts (a third men, two-thirds women), and roughly 18–20% of these were classified as "shock without physical injury" only about 10% of these people were admitted to hospital, and then perhaps only until the following morning During the same period the Ministry were giving injury allowances for the effects of "shock originating from direct exposure to bomb explosion or blast" to about 100 persons a week , and roughly about 5% of those receiving injury allowances were cases purely of "shock" as thus defined These figures, however, are approximate and have, of course, changed from time to time The average period of incapacity for those on allowances for "shock" was about five weeks This would not necessarily cover the period during which symptoms were incapacitating, nor imply that the disability was directly attributable to the bombing , the fallacies are much the same as those familiar in industrial compensation for injury

It can be urged that those who claim benefit for "shock" may not be as numerous as those who might but do not , and that only those who have been in the near vicinity of a bomb explosion are likely to come under the notice of the Ministry of Pensions, yet neurosis attributable to war conditions might occur in others less dramatically exposed to stress Because of this, and because it is difficult to determine whether a patient's neurotic illness is due to the war or not, the following data have been obtained from a doctor in general practice in London whose qualifications and careful records make his information peculiarly trustworthy. They show the variations that have occurred in the incidence of neurotic illness since the war

A LONDON GENERAL PRACTICE

The doctor had about 3000 private patients on his books , they were of the (chiefly lower) middle class, and can be taken as a fair sample of the people of the district, except that the proportion of women to men was unduly high (2 1) owing to the inclusion of the wives of panel patients (i e , of men earning and living on a weekly wage of not more than £5, and who were therefore entitled to National Health Insurance benefit though their wives were not) The number of patients of all kinds seen by this doctor between September, 1940, and May, 1941, was 740 ; the comparable figure for 1937 (January to May, September to December) was 970 , 1937 was selected as the last year free from threats and rumours of war This falling off would correspond to the fact that many women and children had been evacuated, and men had joined the Services Thus 115 children were seen in 1940–41, as against 174 for the corresponding period of 1937

* Report prepared at the request of the Medical Research Council.

Notes and News

University of Oxford

In congregations held on July 18 and 25, the following degrees were conferred

DM—J M L Burtenshaw

MCh—A H Hunt and R H Gardiner

BM, BCh—M H M Gilbertson, J F D Frazer, D S Parsons, J L Boldero, J D Little, R F B Bennett, Q J G Hobson, W D M Paton, W A Briscoe, H G Farquhar, J D Green, J Pinching, K W Lovel, S L H Smith, *J M Jefferson, *H J C J L'Etang R H Scott, R Bryce Smith, P J Crerar, D M Hamilton, R Powell, D A McDonald, N G D Campbell, R H Jackson, A K Tyler, A M M Wilson E Shephard, W B Armstrong, E L H Jones, G A Neligan O P Silver, J J W O H Tobin, Constance M Ormrod, *and M R Mullins

* In absence

University of Cambridge

At recent examinations the following were successful

DMRE

Part I—Olga Bauerova Phyllis Burvill Holmes, Francis Freund, Benzion Kounine, Arnost Preiss, and Ernst Rachwalsky

Part II—G K F Cohen, R M Crichton Timothy Culloty, Francis Freund Maria E Grossman, H T Halper, H R C Hay, C J C G Hodson D A Jennings M B Leitch J M Mennell, D J Mitchell, R G Moffat, J Y Rabinowitch, Katharina Rosenkranz, A W Simmins, J H Smitham, and Lilian H Walter

University of London

Mr B W Windeyer has been appointed to the new chair of radiology at Middlesex Hospital medical school (see the *Lancet*, 1942, i, 508)

Mr Windeyer graduated from the University of Sydney in 1927, obtaining the Edinburgh surgical fellowship three years later He took the DMRE in 1934 and was elected to the fellowship of the Faculty of Radiologists in 1940 He has been on the staff of the Middlesex Hospital since 1931, and in 1937 was appointed medical officer in charge of the Meyerstein Institute of Radiotherapy His published work includes papers on the use of radiotherapy in urology and in non malignant uterine hæmorrhage

Mr F G Young, DSc, a member of the scientific staff of the Medical Research Council, has been appointed to the chair of biochemistry at St Thomas's Hospital medical school, and Mr Alexander Lawson, PhD, lecturer in chemistry at University College, Southampton, has been appointed to the readership in organic chemistry at the London (R F H) School of Medicine for Women

Scottish Conjoint Board

At recent examinations of the board of the Royal Colleges of Physicians and Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow the following were successful

LRCP & SE, LRFP & S

G E Barnard, K H Bayatti, W L Bilsland, William Brydone, B H Budoff, R S David A R N Dhanji, Jess Diamond, E S M Douglas M R El Sairaff, A H Esmat, M S A El Hamid, C C Haupt, El S A K Himmat, P S Huck C L Isitt, H E Katz, Ian McKechnie, Robert Mitchell, L E Mosscrop, M A Motagalli, A C Muir, J A Murdoch, J A M'Ratcliffe, Harold Rosenberg, Albert Schmookler, Monroe Schneider, J S Seaton, S P Selvadurai, J K K Stielau Bernard Stillerman, Seymour Tenzer, I A M Thomson, Ramapillai Vannithamby, Harry Walker and Isidor Wolff

Manfred Gross, MD Berlin, as graduate of a recognised foreign university, was also admitted a licentiate

Royal College of Surgeons of Edinburgh

At a meeting of the college on July 23, with Mr J W Struthers, the president, in the chair, the diploma of honorary fellowship was presented to Lieut General Alexander Hood, DG AMS, and to Prof A T Jurasz, dean of the Polish Medical Faculty of the University of Edinburgh The following were admitted to the fellowship

George Bankoff, MD Florence, Hassan Din MB Punjab, T J Evans, MB Lond, Dora J B Falconer, MRCS, A P Gracie, MB Edin, J D Hallissy MB NUI, A W Kay, MB Glasg, G R Nicks MB NZ D L Savill, MB Ldin, J A E Watts, MRCS, and E B Wild, MRCS

Glasgow Smallpox Epidemic

Up to July 10 there were 39 confirmed cases of smallpox in Glasgow, including 10 cases from the ship There were no further cases until July 20 when one was discovered in a mental hospital On July 21 a Glasgow girl, holidaying in London, was admitted to hospital there as a case of smallpox On July 24 a further case was diagnosed in Argyllshire There have been 7 deaths among these 42 patients

Royal Medical Benevolent Fund

At a quarterly council meeting on July 28 Sir Arnold Lawson, who was re elected chairman, said that his personal letter sent out with the report had got in more subscribers and increased the number paying by banker's order Several new legacies were announced Figures submitted by the secretary showed that the total book value of investments, the amount of money distributed annually, the subscription income, and the dividend income, had all been doubled during the last 15 years During the same period the working expenses had only gone up from £1428 in 1927 to £1617 in 1941 The case committee reported the growing difficulties of beneficiaries in these days of higher living expenses The unwritten rule to give no grant to anyone with an income of over £100 may have to be relaxed The secretary would impress expectant testators with the need for accurate terminology, their bequests are *frequently so worded as to make it* difficult to decide to what body the legacy was left The ambiguity may sometimes nullify the legacy It was decided that in future new applicants need not obtain the supporting signature of a subscriber, the recommendation of any medical practitioner will be enough

More Approved Names for Drugs

The General Medical Council has approved names for three more substances now being produced, or likely shortly to be produced, by British manufacturers

Approved names	*Previous names*
Dienœstrol	Di *p* hydroxyphenylhexadiene
Pheniodol	Biliselectan
Ethisterone	Ethinyltestosterone Lutocyclin Lutogyl Pregneninolone Progestoral Proluton C

The question of including these substances in the British Pharmacopœia is under consideration

---

A new Portugese medical journal called *Amatus Lusitanus* is designed to carry on the tradition of Portuguese medicine set by Amato Lusitano, a worthy contemporary of Andreas Vesalius and Ambroise Paré The first issue contains a well illustrated article on the structure and functions of the hypophysis by A C da Costa, a study by J Cutileiro of the types of pneumococci found in 69 cases of lobar pneumonia and the relation between the type of infection and the symptoms and prognosis, a lecture on malaria by F J C Cambournac, and a report of a case of acute pemphigus by J Esteves The general standard is high An English summary of each article would increase the value of the journal to most English readers, only one article in the first number has such a summary

ERRATUM—In the letter on "Dangers of Dulcin" (p 141 of our last issue, 11th line from end), for rapidly read *sapidly*

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

Births, Marriages and Deaths

BIRTHS

CURRAN—On July 21, at Wolverhampton, the wife of Dr T P Curran, of Stafford—a daughter

ELLIS JONES—On July 27 at Woking, the wife of Surgeon Lieutenant E Ellis Jones RNVR—a daughter

JOHNSTON—On Aug 1, in London the wife of Dr Colin McKe Johnston, BDS—a son

RUSSELL—On July 24 at Oxford the wife of Major W Ritch Russell, RAMC, of Edinburgh—a daughter

MARRIAGES

MILNE—MCKENDRICK—On July 25 at Beaconsfield, Frank Milne to Margaret Elizabeth McKendrick, MRCS

DEATHS

ASTON—On July 29, at Seaview, Isle of Wight, Richard Norm n Aston, MRCS

BUCKHAM—On July 31, at Hereford, Frederick Buckham, LRCP, formerly of Cardiff, aged 94

DREWITT—On July 29 in London, Frederic George Dawtrey Drewitt MD OXFD, FRCP, aged 94

FRASER—On July 27, at Caistor, Lincolnshire, Alexander Fraser, MB EDIN JP

NEISH—On July 27 at Tunbridge Wells, William Alexander Neish, MB GLASG

TALLACK—On Aug 1, John Reginald Arthur Tallack, MB LPOOL, of Grays, Essex, aged 40 develops or is aggravated during the war, war stress had not been responsible for this in a quarter of the previously healthy, and in a fifth of those with previous neurotic history Moreover, recovery or great improvement is the rule in those who were not already neurotic before the war

It is interesting to see whether the months during which London was heavily bombed showed a heavier incidence of neurosis Fig 1 (based on financial returns which have been found to correspond closely to attendances) shows that between September, 1939, and September, 1940, the number of patients who attended showed much the same rise and fall as in previous years, except for slight deviations attributable to the first evacuation from London in the early months of the war, and a smaller exodus at the time France capitulated From September, 1940, however, the curve is quite different, and shows that there was either very much less illness than might be normally expected, in the autumn and early winter of 1940, or—obviously the more appropriate explanation—that the population of the district was declining It follows that a comparison of the absolute figures of neurosis for the months between September, 1940, and May, 1941, with each other, or with those of the corresponding months of previous years, would be misleading, and that any month by month fluctuations in the amount of neurosis could best be recognised by a monthly fluctuation in the proportion of neurotic to physical illnesses seen On such a basis it would seem that the percentage of neurosis was higher in the months September, October, November, 1940 (figs 2 and 3)

MERSEYSIDE

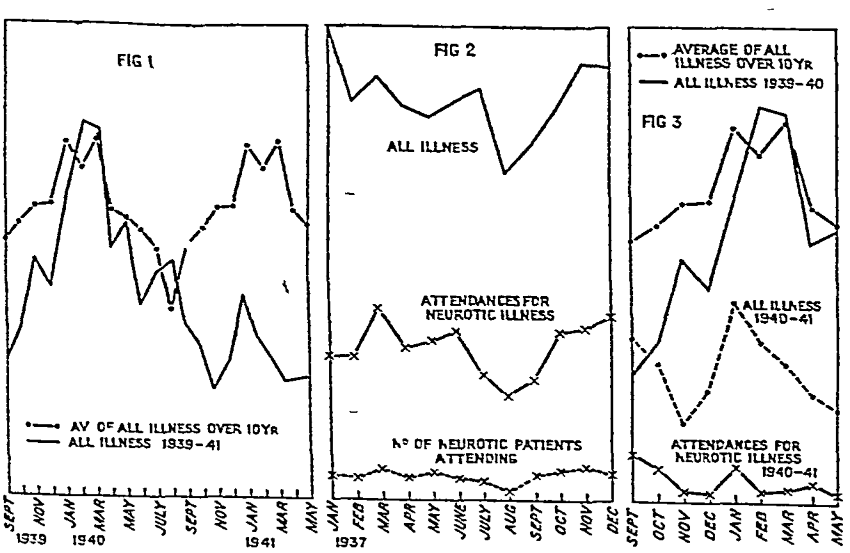
Data have been obtained, particularly about Liverpool, from the professor of medicine (who is physician at the Royal Infirmary), three psychiatrists in charge of outpatient clinics in Liverpool and six general practitioners (three in Liverpool, Birkenhead and Wallasey—bombed areas—and three in reception areas to which Merseyside people betook themselves after the raids) Their evidence is not discrepant The Liverpool doctors—psychiatrists and others—state that they have not observed any increase in the incidence of psychoneuroses as a result of war, and the doctors in reception areas say they have seen “very few who show nervous disturbances, or more than the usual anxiety which we all feel these days” , “no evidence of any numerical increase—a few who were abnormally nervous people before were somewhat worse”

TABLE III—DATA FROM THE SAME GENERAL PRACTICE FOR 1937

Patients seen in 1937	No.	Av age (yrs)	Children 14 or under	Av age excluding children	Per cent of same sex	Per cent of total illness
Female—						
For physical illness only	575	37	125	45	69	46
For nervous symptoms	146	47	4	48	17 } 31	12 } 21
For neurosis	115	41	4	43	14	9
	836		133			67
Male—						
For physical illness only	332	32	107	45	83	27
For nervous symptoms	34	40	2	43	8 } 17	3 } 6
For neurosis	35	35	0	35	9	3
	401		109			33
Total	1237		240			

Of total number	67% female, 33% male
Of the females	69% physical illness 17% nervous symptoms 14% neurosis (31% nervous illness)
Of the males	83% physical illness, 8% nervous symptoms, 9% neurosis (17% nervous illness)
Of the total	73% physical illness 15% nervous symptoms 12% neurosis (27% nervous illness)
Of physical illness	63% female, 37% male
Of nervous illness	40% nervous symptoms in female 35% neurosis in female (75% female) 12% nervous symptoms in male 13% neurosis in male (25% male), i e, 52% nervous symptoms, 48% neurosis

However, one practitioner (in Llandudno) reported having seen many cases of “mental fatigue and nervousness which soon improved in our more fortunate surroundings The patients in particular with a high blood-pressure and the associated nervous make-up suffered badly but again responded well to rest and treatment My partner bears out what I have said, and we might add that we not only have to deal here with evacuees from Liverpool but are also in charge of two large working-class convalescent homes for the Birmingham districts, which would be expected to bring to our notice a disproportionately higher number of cases of psychoneurosis, if they existed Among these patients also, one does not seem to find a higher proportion of such psychoneurotic patients than prior to the war” And another in Rhyl says · “except for the initial shock and a purely temporary phase for a short time afterwards I have not seen neurotic reactions in the large number of people who have come from the large towns where they have been bombed very severely. I have seen a number of anxiety states but they have all been in people who have not been bombed at all (anticipation neurosis)”



Figs 1-3—Experience in a London general practice. Fig. 1 shows the incidence of all illness from September 1939 to May 1941 compared with the previous ten-year averages In fig 2 the numbers of attendances and of patients attending for neurotic illness in 1937 are compared with the attendances for all illness in the same year Fig 3 shows the attendance for neurotic illness and all illness in 1940-41 compared with attendances for all illness in 1939-40 and in the previous ten years

These curves have been computed in part from financial returns and though their vertical scales are comparable it is not possible to express them in figures.

The demeanour of injured persons was described as “patient and stoical I had less trouble here than in an ordinary hospital ward No complaints smiles occasionally mixed with tears, if one inquired about relatives, were usual These patients, having tasted the bitterness of homes gone and injuries sustained were grateful for any attention and had a serenity and calm which might be due to the fact that, having experienced their worst fears and come through, they were content to await the future and not rush to meet it—no evidence here of neurosis, either hysterical or depressive”

One of the psychiatrists (who has an outpatient clinic at the Royal Southern Hospital) mentions that “some of one's old chronic cases seem to be improved in present circumstances” And, while pointing out that the falling off in attendances is partly accounted for by the unwillingness of patients from outlying districts to come into Liverpool, he discredits the view that there are large numbers of war-stress patients who do not get to the psychiatrists, he adds that discussion with his

TABLE I—DATA FROM A LONDON GENERAL PRACTICE IN NINE MONTHS OF WAR

—	—	1940				1941					Total

* Including a number not treated for neurosis but seen for other reasons

Average number of attendances for patients during Sept 1940 to May 1941 non neurotic 4 02, neurotic illness 4 08 (+ other attendances for non neurotic illness)

Patients seen Jan 1940 to Aug 1940 and not seen since (both neurotic and non neurotic)	556
Patients seen Sept 1940 to May 1941	740
	1296
Patients seen 1937–39 and not seen since	1620
Estimated total number of patients (not on panel list)	2916

The number of patients seen for neurotic disturbance, from September, 1940, to May, 1941, was 244—that is, a third of all patients seen had a neurotic illness during the period covered (tables I and II) The average number of attendances was the same for those with neurotic illness as for those physically ill, unless the physical illnesses of neurotics are also reckoned, in which case they have a higher average number of attendances During 1937 the proportion of those neurotically ill had been lower (27% of all patients seen, table III), but a third of all female patients seen were complaining of neurotic disorder, whereas only a fifth of the men did so An increase in the proportion of women seen in 1940–41 would therefore be likely to lead to a higher proportion of neurotic patients The proportion of men to women, however, among all patients seen between September, 1940, and May, 1941, was the same as it had been in 1937, and the proportion of men to women among those with nervous illness was also the same during the two periods in question The rise, therefore, in the proportion of neurotic illness did not depend on a change in the sex ratio

The absolute number of neurotic persons seen in 9 war months (September, 1940, to May, 1941) was the same (between 240 and 250) as it had been for the corresponding period two years before the war, but as the total number of all patients seen had fallen off (from 970 to 740), it appears that there had been a slight rise since the blitz in the amount of neurosis in the available population Of these neurotic patients rather more than half (now, just as in 1937) have a straightforward neurosis, and the remainder have prominent neurotic symptoms masquerading as physical disease or due to physical disease Of the 1940–41 neurotics, 20% had not previously had a neurotic illness, 74% of them were known to have had previous neurotic disturbance, which had been made worse by the war in most cases, in the remaining 6% reliable previous data were not available In two-thirds of the neurotics the conditions had developed, or been aggravated, since the war The prognosis was good in those 49 patients who had hitherto been free from neurotic trouble 34 of them recovered or improved greatly, whereas only 24 recovered or improved greatly out of the 102 who had a previous history of neurosis

As to the part played by actual war stress, including air-raids, there was evidence that this was one of the causes of the illness in three-quarters of the patients who were now having their first neurotic attack, and that it was partly responsible in four-fifths of the patients who had a history of previous neurotic trouble (table II) Air-raids alone had played a causal part in an eighth of the previously neurosis-free and in a sixth of those with previous neurotic history The severity of the neurotic illness was much greater in the "aggravated" group who had a history of previous neurosis than in the others, only 4% of the previously neurosis-free had now got a severe neurosis as contrasted with 20% of the "aggravated" group

From all this it follows that a severe neurosis hardly occurs as a war phenomenon except in people who had been neurotic before the war, and that when neurosis

Raids a factor in 54% improvement in at least 47%

actual or potential—were among the first to evacuate Nevertheless it cannot be said that there is evidence of any notable increase in the incidence of neurosis Coventry has suffered many previous raids, and it may be that these served to eliminate the more nervous people by evacuation prior to the big raid "

A psychiatrist confirms the foregoing, in the main (May, 1941)

"The numbers of new cases at the psychiatric outpatient department at the Coventry and Warwickshire Hospital have hardly altered since the air raids began On the average 5 new cases are seen each week Hardly any hyperacute neuroses have been referred either to the department, to the County Mental Hospital or to the Regional Neuro Psychiatric Emergency Hospital During the past few months there has been a trickle of anxiety states and hysterics that could be attributed more or less directly to the air raids These, however, hardly ever appear for a few weeks after the raid in question In the general emergency hospitals to which I am attached as consultant, one sees a few more acute psycho-neurotic conditions, often associated with physical injuries The chief psychiatric problem after a big raid is in coping with early senile cases who become maladjusted, and mental defectives who should years ago have been institutionalised Both these types seem easily to become unstuck when having to live in a shelter My general impression is that the number of neurotic disturbances is considerably higher than we realise, but that the cases just do not get treatment, that is not to say, however, that the majority of them do not make a spontaneous recovery "

MANCHESTER

In Manchester which has had severe, but relatively few, raids there has not been any increase in the number of patients attending psychiatric outpatient clinics, nor according to social workers has there been any demand for psychiatric help among the adult evacuees in the quieter regions around Manchester A previous history of neurosis, or of high-grade mental defect has been found in the patients with neurotic reactions to raids

LONDON

The number of new patients seen at various psychiatric outpatient departments in London was 4330 in 1940, as against 5945 for the same clinics in 1939 These figures cannot be taken at face value since there were many other factors influencing them besides the actual amount of neurotic illness for instance, many of the clinics were working with reduced staff and much reduced hours of attendance They suggest, however, that there was no increase in neurotic illness

Further loose data about the London population indicate that, as was reported from some provincial regions, the reactions to bombing may be delayed Thus in the middle of September hundreds of homeless people from East and West Ham had been moved to rest centres in Essex They were depressed, as a group, and thus contrasted strongly with the cheerful demeanour of those seen in similar rest centres in London itself, to which the people had come immediately after the raid However, these people did not need a doctor's attention Similarly among a large number of London evacuees seen in a Yorkshire reception area after having been bombed out, intolerance and irritability were noticed, in contrast to the usual Cockney good humour and endurance Among 1600 homeless people moved to another area (which was itself in the gun barrage, and where many bombs were dropped) and billeted there, there were 130 who during October, November and December, 1940, came under the notice of a psychiatric social worker as being "nervous", 45 of these 130, however, were under the age of 16, and only one of the 85 adults became a hospital inpatient, 12 attended a psychiatric outpatient clinic (usually only for one interview with the psychiatrist) "In many cases the difficulties of a new environment, separation from other members of the family, and loneliness seemed as important factors as the bombing experiences they had had—minor environmental adaptations and friendly visiting were sufficient to put them right " Most of the cases cleared up well

A special problem in the civilian population is presented by those in the ARP services, and especially in the fire-fighting service (AFS) These men are employed by the local authority, and any with incapacitating nervous symptoms are, in the London area, officially referred to a Maudsley psychiatric clinic for advice The total number of men, among the thousands of London's AFS, who have been referred to various Maudsley outpatient clinics for advice either officially or by their own doctor, was 72 between September, 1940, and May 30, 1941 There are, of course, some among the men who are being treated by their private doctors for neurotic symptoms, but any who have had to stop work on account of their symptoms would be referred to the clinics mentioned A few of the AFS men have been seen, after heavy exposure, suffering from exhaustion comparable to that seen in the soldiers evacuated through Dunkirk, and they show similar rapid recovery after rest, though they may turn out to have had a predisposition to neurosis, and to be henceforward less able to bear the stress of their ARP work

Among those doing the less strenuous and dangerous forms of ARP work (e g, telephonist at a post) instances of improvement on their previous mental health are reported, they have a definite and satisfying job Similarly an investigation made in the spring of 1940 on chronic neurotics attending outpatient clinics showed that a proportion had improved since the war gave them interests previously lacking On the other hand, many persons who had been uneasy and anxious during the first year of the war (when there was no tangible danger but much room for morbid and exaggerated fears) were able to settle when they had experienced the real thing and knew the worst There are no reliable figures showing the extent to which this observation, made by observers in different parts of the country, held good for the neurotic population as a whole

It would be wrong to assume, as some have, that socially undesirable behaviour, especially evasion or timidity in the face of danger and privation, are the only forms of neurotic reaction evident, obsessional neurosis, for example, is seen which does not conflict with social duty and capacity to perform it, many patients with anxiety neurosis are courageous and enduring, and some of those who eventually become incapable of carrying on with their work because of neurosis have long done good service in spite of their symptoms Their illness is incapacitating, like physical disability, if criteria of moral and social responsibility are introduced, they lead to the conclusion that undesirable or blameworthy manifestations of neurosis and psychopathic personality are far less often seen in neurotic civilians than in neurotic soldiers This does not imply a reflection upon the soldiers (who are mostly yesterday's civilians) but is an outcome of the different environmental and emotional causes at work in the two groups Discussion of the causes of neurotic symptoms would be irrelevant here as is also discussion of the forms neurotic illness takes when these war-time causes are operative An account of the types of unhealthy mental reaction seen among the civilian population may be found in various articles (Felix Brown 1941, Harris 1941, Pegge 1940) There is nothing new in these types of reaction, nor in the semistupor described in a few cases as an immediate reaction to bombing

PSYCHOTIC REACTIONS

So far neurotic reactions have been considered The common distinction between neurosis and insanity is, however at bottom so arbitrary and vague, except for legal and administrative purposes, that many cases fall equally well into either category Thus among those committed to observation wards on a relieving officer's order since the war there have been some who would in ordinary times be treated as neurotics in an outpatient department or an ordinary hospital ward

Admissions to observation wards in London, the best provided and organised city in this regard, have varied not only according to the number needing admission but also according to the available accommodation, several large observation wards having been blasted or set on fire The Dulwich observation ward serves a population of approximately 700,000, in a district which has been severely and repeatedly attacked from the air Between September, 1940, and February, 1941, 435 patients were admitted—an increase of 25% on previous figures But probably this does not hospital colleagues in all departments and with general practitioners confirms his opinion, but "of course I am excluding the emotional distress and mental fatigue of short duration, following on severe or prolonged bombing—such states are obviously widespread but do not constitute neuroses" This tallies with the Llandudno doctor's comment above

The two other psychiatrists report that in two first line hospitals, which received respectively 578 and 743 air raid casualties, there were only two instances of "acute mental or nervous distress," and they remark that inquiries about first-aid posts elicited little difference of experience from the above there were instances of "very minor and transient alarm" such as could be dealt with by ARP personnel They too report that continuous and intensive air bombardment has not been followed by any immediate rise in the number of cases referred to psychiatric outpatient clinics As to later effects, they have found that persons known to have been unstable before the air raids "remain relatively unaffected by blitz conditions, their activities and even their responses to treatment pursuing a normal course." These psychiatrists, however, say in general terms anxiety states, mildly depressed conditions, and states of transient confusion and mental exhaustion have been found to follow enemy action, these have been of varying duration, a notable feature has been their incidence among elderly persons, and adolescents Among the cases in civil defence workers the elements of fatigue, extreme mental and physical exhaustion and previous unfamiliarity with gruesome circumstances, as experienced by regular and auxiliary firemen, rescue parties and first aid workers, have naturally been of marked contributory significance Another Liverpool psychiatrist says that he has noticed that half of his patients are worse since the war, a quarter are better, and a quarter unaffected most of those who did not improve were unmarried men of military age

From Liverpool and Birkenhead come such reports as "the commonest neurotic reaction in this area has been one of flight to the safety areas of those that remained the majority are fairly cheerful, and the commonest reactions of which the minority complain are sinking feelings in the epigastrium, insomnia (lying awake listening for sirens), a few cases of diarrhœa at night during the raid and for the following day", "I run a private practice ranging from the better class industrial workers upwards all my patients and friends have stood up to the raids much better than I expected A few, mostly women of middle age, have been upset and found themselves weeping for no reason at all the exhibition of a little bromide has been all that was necessary to cause disappearance of their symptoms I have seen very few people seriously affected but in each case there has been a definite history of mental instability many who have had very unpleasant experiences—loss of home, narrow escapes, loss of relatives, &c —continue to live in the danger zone, and whilst admitting, as do we all, that they do not like the raids, nevertheless face them Many patients of over 70 have stayed put and do not appear to be seriously affected either by fear or loss of sleep"

It is of interest that the doctors in Liverpool trained 18 volunteers as auxiliary mental-health workers for service in and after raids, but none of the 18 has been required there was no such work for them to do

BRISTOL

The staff of the Bristol Child Guidance Clinic made a survey during January, 1941, of people sleeping in a tunnel, housing 2200–3000 persons Fifty families were investigated totalling 172 persons These people were spending twelve or more hours every night in the tunnel, they had only what meals they could bring with them or prepare on the spot, and many, in the unscheduled part of the shelter, were dossing on bedding on the earthen floor

"The striking result of this survey was the very high proportion of individuals suffering from well marked nervous symptoms, generalised fear of air raids was universal and was discounted for the purposes of the investigation The subjects considered nervous were either diagnosed as such by their own doctors or showed well marked symptoms of psychological illness Of all the (family) units investigated 62% included one or more members suffering from psychological illness, 50% of these units included members receiving treatment from doctors, hospitals or clinics for 'nervous' disorders Those persons who stated that they 'had no faith in Anderson shelters' nearly always had psychological signs, and this could almost be taken as a psychological symptom. Damage to the home (58%) or absence of domestic shelter (74%) were aggravating factors In spite of considerable hardships involved in travelling long distances to the tunnel, difficulties in preparing food, and unsatisfactory sleeping accommodation, *the great majority of these nervous subjects have improved in health since they have spent their nights in the tunnel*" The psychiatrist points out that "the determining causes of this troglodyte life act on the family as a whole, whether they be absence of shelter, damage to the home, or the presence of a neurotic member of the family, only in very rare instances does the neurotic come alone Usually, he or she is accompanied by one or more members of the family, though the more stable members of the family may elect to stay at home and assist in fire watching and other ARP duties" Consequently, the shelter population would contain an unusually high proportion of neurotic and otherwise unstable subjects This would apply less to London, where the available shelter accommodation was much greater

The appendix to the Bristol report, containing brief case-histories of the 50 families, bears out the statements about the high incidence of neurosis

In the middle of February, 1941, the same investigators visited 25 families who had first been seen in the rest centre after being bombed out, and were now installed in a house of their own again, 8 of the families had been evacuated because of delayed-action bombs, the other 17 families (73 persons) had had their houses demolished, 3 of the families (19 persons) having been buried for a time in the ruins or in their Anderson shelters and then dug out, yet only 1 of these 19 persons showed even slight psychological symptoms

"Many of these homeless people who had lost most or all of their possessions appeared dazed or stupid in the rest centres, but all of them improved remarkably once they had been installed in a house of their own, and appeared quite different Naturally, the elderly proved less adaptable and more uprooted But on the whole adaptation was good As was to be expected, there was a relatively high incidence of psychological symptoms in these victims of enemy action, 19 persons out of 73 (26%), but only 3 men, had stopped work on account of these symptoms, and 2 of these were over sixty"

It is mentioned that in quite a number of these families, as it happened, the mother was of low intelligence, and *even in some cases actually feeble-minded*

BIRMINGHAM

From other big cities comes less detailed information A psychiatrist in Birmingham writes (June, 1941) of the rather extraordinary absence of mental ill health

"I have, however, been getting more cases of neurosis precipitated by or increased by air raids than I had some months back, and I believe there will be a fairly big time lag before the effects can be assessed Also my people are ashamed to complain of their symptoms, and thus are put on the panel and tend either to recover or become chronic before they are passed on for psychiatric treatment, while others again evacuate themselves"

A group of 50 unselected cases, 25 male, 25 female, treated at the Midland Nerve Hospital, Birmingham, between November, 1940, and May, 1941, was analysed 21 of them came from the "target" area, 16 from the periphery of the city, and 13 from the suburbs or country In 4 cases—all diagnosed "*hysteria*"—*this condition had been precipitated by raids*, in 13 cases (8 of anxiety, 3 of depression, 2 of schizophrenia) raids had aggravated a pre existing condition, in 6 patients the illness was only slightly affected, and in 27 it was not affected, by raids

COVENTRY

In Coventry the medical officer of health reported after the November, 1940, raid

"Many cases of mental distress found their way to the first aid posts for rest and sympathy They can best be described as having been stunned by events In the main their condition soon became normal On the whole the reaction of the population was one of calm defiance Doubtless there was a proportion of neurotic subjects, notably amongst the hasty evacuees Actually there has been a decrease in the number of patients attending the psychological outpatient clinics held twice weekly in the city This is probably due to (*a*) the decrease in the civic population due to evacuation, and (*b*) the likelihood that the clinic patients—

actual or potential—were among the first to evacuate Nevertheless it cannot be said that there is evidence of any notable increase in the incidence of neurosis Coventry has suffered many previous raids, and it may be that these served to eliminate the more nervous people by evacuation prior to the big raid "

A psychiatrist confirms the foregoing in the main (May, 1941):

"The numbers of new cases at the psychiatric outpatient department at the Coventry and Warwickshire Hospital have hardly altered since the air-raids began. On the average 5 new cases are seen each week. Hardly any hyperacute neuroses have been referred either to the department, to the County Mental Hospital or to the Regional Neuro-Psychiatric Emergency Hospital. During the past few months there has been a trickle of anxiety states and hysterics that could be attributed more or less directly to the air-raids These, however, hardly ever appear for a few weeks after the raid in question In the general emergency hospitals to which I am attached as consultant, one sees a few more acute psycho-neurotic conditions, often associated with physical injuries The chief psychiatric problem after a big raid is in coping with early senile cases who become maladjusted, and mental defectives who should years ago have been institutionalised Both these types seem easily to become unstuck when having to live in a shelter My general impression is that the number of neurotic disturbances is considerably higher than we realise, but that the cases just do not get treatment , that is not to say, however, that the majority of them do not make a spontaneous recovery."

MANCHESTER

In Manchester which has had severe but relatively few. raids there has not been any increase in the number of patients attending psychiatric outpatient clinics, nor according to social workers has there been any demand for psychiatric help among the adult evacuees in the quieter regions around Manchester. A previous history of neurosis, or of high-grade mental defect has been found in the patients with neurotic reactions to raids

LONDON

The number of new patients seen at various psychiatric outpatient departments in London was 4330 in 1940 as against 5945 for the same clinics in 1939 These figures cannot be taken at face value since there were many other factors influencing them besides the actual amount of neurotic illness for instance many of the clinics were working with reduced staff and much reduced hours of attendance. They suggest however. that there was no increase in neurotic illness

Further loose data about the London population indicate that as was reported from some provincial regions. the reactions to bombing may be delayed Thus in the middle of September hundreds of homeless people from East and West Ham had been moved to rest centres in Essex. They were depressed. as a group, and thus contrasted strongly with the cheerful demeanour of those seen in similar rest centres in London itself to which the people had come immediately after the raid However, these people did not need a doctor's attention. Similarly among a large number of London evacuees seen in a Yorkshire reception area after having been bombed out. intolerance and irritability were noticed, in contrast to the usual Cockney good humour and endurance Among 1600 homeless people moved to another area (which was itself in the gun barrage. and where many bombs were dropped) and billeted there there were 130 who during October, November and December. 1940, came under the notice of a psychiatric social worker as being 'nervous " 45 of these 130 however. were under the age of 16, and only one of the 85 adults became a hospital inpatient ; 12 attended a psychiatric outpatient clinic (usually only for one interview with the psychiatrist) 'In many cases the difficulties of a new environment, separation from other members of the family, and loneliness seemed as important factors as the bombing experiences they had had—minor environmental adaptations and friendly visiting were sufficient to put them right.' Most of the cases cleared up well.

A special problem in the civilian population is presented by those in the ARP services and especially in the fire-fighting service (AFS) These men are employed by the local authority, and any with incapacitating nervous symptoms are, in the London area. officially referred to a Maudsley psychiatric clinic for advice The total number of men. among the thousands of London's AFS, who have been referred to various Maudsley outpatient clinics for advice either officially or by their own doctor, was 72 between September 1940 and May 30 1941 There are, of course, some among the men who are being treated by their private doctors for neurotic symptoms, but any who have had to stop work on account of their symptoms would be referred to the clinics mentioned A few of the AFS men have been seen, after heavy exposure, suffering from exhaustion comparable to that seen in the soldiers evacuated through Dunkirk; and they show similar rapid recovery after rest, though they may turn out to have had a predisposition to neurosis, and to be henceforward less able to bear the stress of their ARP work

Among those doing the less strenuous and dangerous forms of ARP work (e.g , telephonist at a post) instances of improvement on their previous mental health are reported , they have a definite and satisfying job Similarly an investigation made in the spring of 1940 on chronic neurotics attending outpatient clinics showed that a proportion had improved since the war gave them interests previously lacking On the other hand, many persons who had been uneasy and anxious during the first year of the war (when there was no tangible danger but much room for morbid and exaggerated fears) were able to settle when they had experienced the real thing and knew the worst There are no reliable figures showing the extent to which this observation made by observers in different parts of the country, held good for the neurotic population as a whole

It would be wrong to assume, as some have, that socially undesirable behaviour especially evasion or timidity in the face of danger and privation, are the only forms of neurotic reaction evident , obsessional neurosis, for example, is seen which does not conflict with social duty and capacity to perform it . many patients with anxiety neurosis are courageous and enduring, and some of those who eventually become incapable of carrying on with their work because of neurosis have long done good service in spite of their symptoms Their illness is incapacitating, like physical disability ; if criteria of moral and social responsibility are introduced, they lead to the conclusion that undesirable or blameworthy manifestations of neurosis and psychopathic personality are far less often seen in neurotic civilians than in neurotic soldiers This does not imply a reflection upon the soldiers (who are mostly yesterday's civilians) but is an outcome of the different environmental and emotional causes at work in the two groups Discussion of the causes of neurotic symptoms would be irrelevant here: as is also discussion of the forms neurotic illness takes when these war-time causes are operative. An account of the types of unhealthy mental reaction seen among the civilian population may be found in various articles (Felix Brown 1941. Harris 1941, Pegge 1940) There is nothing new in these types of reaction, nor in the semistupor described in a few cases as an immediate reaction to bombing

PSYCHOTIC REACTIONS

So far neurotic reactions have been considered. The common distinction between neurosis and insanity is however. at bottom so arbitrary and vague except for legal and administrative purposes that many cases fall equally well into either category Thus among those committed to observation wards on a relieving officer's order since the war. there have been some who would in ordinary times be treated as neurotics in an outpatient department or an ordinary hospital ward

Admissions to observation wards in London, the best provided and organised city in this regard. have varied not only according to the number needing admission but also according to the available accommodation, several large observation wards having been blasted or set on fire The Dulwich observation ward serves a population of approximately 700 000, in a district which has been severely and repeatedly attacked from the air Between September, 1940, and February, 1941, 435 patients were admitted—an increase of 25% on previous figures But probably this does not indicate an actual rise in the incidence of patients needing admission, for the 250 beds of the Maudsley Hospital, barely a mile away, were no longer available, and its outpatient department was temporarily closed, moreover, an observation ward in Fulham had been bombed and its clientele was for a while transferred to Dulwich There was, however, a relative increase in senile cases, as has been reported from many other bombed towns Elderly people are reluctant to leave their homes, no matter what the danger, and while some bear bombardment with remarkable indifference, others find the dislocation of their lives too much for them, their accustomed rut is not there for them to run in, their relatives who looked after them are dispersed, and in the confusion they become helplessly confused Of the 435 patients admitted, 32% were diagnosed senile dementia, 20% other organic disorders, 2% psychopathic personality, and 1% anxiety neurosis or hysteria 20% had a depressive syndrome, 5% mania, and 20% schizophrenia There were in all 13 cases that seemed directly attributable to air raids, and 9 other cases in which the raids had played a minor part in causation The case-histories in Harris's (1941) paper indicate the type of case, and indicate also how a condition apparently attributable to air-raid stress can be at bottom one of general paralysis of the insane or paralysis agitans, the problem (apparent aggravation of physical disease by psychological factors) is one that became familiar to pensions boards in and after the last war

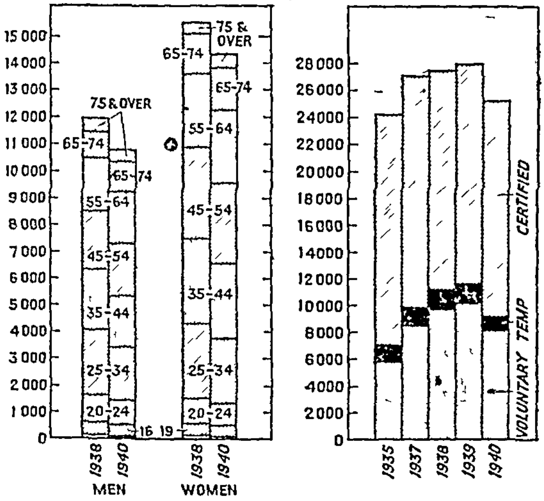

Fig 4—Analysis of admissions to all county and borough mental hospitals in England and Wales during the years indicated

An observation ward in the badly attacked East End of London (Bow) admitted during the four weeks Aug 28 to Sept 24, 1940, 95 patients, whereas during the corresponding period of 1939 the number of admissions had been 120, the decline was chiefly in male cases (39, as against 62 in 1939)

Fluctuations in the population do not make the figures for admissions to all county and borough mental hospitals in England and Wales so difficult to interpret as those of London Total admissions in such hospitals were 8% less in 1940 than in 1938, the falling off was greater among men (9%) than among women (7%) The fall in number of admissions (fig 4) may or may not reflect the changing incidence of mental illness in the population at large Probably it does not Factors of an extraneous nature have operated to keep the number of admissions low, the chief of these being the demands made upon available accommodation in the hospitals by the conversion of many of them either wholly or partly into emergency hospitals for physical illness This may be seen in the changing numbers of voluntary patients admitted The voluntary admissions had until the war been increasing both absolutely and relatively to the certified admissions In 1937 voluntary patients were 31% of all admissions, in 1938 35%, in 1939 36%, but in 1940 they fell to 32% Whereas in 1940 the certified admissions had only diminished by a fiftieth from the 1939 level, the voluntary admissions in 1940 were a fifth less than their 1939 number This falling off was due to administrative action and to the fact that voluntary patients include those in whom admission to the mental hospital may not be imperative The actual numbers of voluntary patients admitted in 1940 had fallen below the 1937 level (fig. 4)

The general age-distribution of all mental hospital admissions in England and Wales remains about the same—most of the cases come from the age groups 25–65, the decade 45–54 supplying the largest quota of women, and the decade 25–34 the largest quota of men The maximum variations between 1938 and 1940 are seen in the age-groups 20–24, 25–34, 35–44, 45–54, where the number of men admitted diminished by 20%, 16%, 15%, 13% respectively, and the number of women by 11%, 13%, 14%, 11% respectively, and in the age groups over 75 where the male admissions increased by 41% and the female by 34%, though the actual numbers are not large and the absolute increase considerably less than the absolute fall in other age-groups If 1939 be compared with 1938 and with 1940, variations are observed especially in the 16–19 age-group. The explanation is not clear, 1939 was, of course, a mixed year partly of peace and partly of war, and male adolescents may have been influenced by the introduction of the Militia Training Bill

There are some indications of mental ill health which do not come under the notice of doctors and hospitals so much as of legal authorities. Suicide is the most prominent of these Recent and reliable data about suicide are not available for England and Wales For Scotland the figures have been published on a quarterly basis

	MALE					FEMALE					
Quarter	1	2	3	4	Total	1	2	3	4	Total	
1938					297					163	(460)
1939	78	91	82	61	312	40	34	43	29	146	(458)
1940	66	68	65	59	258	38	38	38	28	142	(400)

The annual report for 1938 does not provide the data on a quarterly basis The quarterly returns for 1939 and 1940 provide age-groupings, but do not subdivide these according to sex The figures indicate a significant fall in the total suicides for 1940—the total of 400 compares with 458 for 1939 and 460 for 1938 and is the lowest since 1925 If the returns are subdivided into two age-groups, the figures are

	OVER 45 (M AND F)					UNDER 45 (M AND F)					
1938					292					168	(460)
1939	73	85	74	58	290	45	40	51	32	168	(458)
1940	71	61	64	38	244	33	45	39	39	156	(400)

This suggests that among those under 45 there has not been a fall in the frequency of suicide, there may have been a rise The small reduction, from 168 to 156, would be within the normal range of chance fluctuation The under 45's have lost a considerable proportion of their male population to the Army (Army deaths, from whatever cause, are not included in the civilian returns during war-time), and young males normally contribute a heavy percentage of the total suicides under 45

Among the "over 45's" the reduction in 1940 of 16% is significant The size of the population concerned has not changed materially I would not speculate about the reason for this fall in Scotland. Suicide-rates usually fall during war The rate became appreciably lower between 1915 and 1918 in belligerent nations (Great Britain, Australia, New Zealand, South Africa, Germany, Italy, U S A, Japan) and in non-belligerents too (Sweden and Switzerland) Nor is this wholly accounted for by the high number of men within the suicide-age who are withdrawn into fighting services In England and Wales there was a fall of 10% in the suicide-rate for women during the last war

ALCOHOL

If the consumption of alcohol had risen greatly since the war it might suggest an increased amount of mental instability in the population—as the cause of the drunkenness, and perhaps also as an effect of it Figures, however, can easily be misleading here

By agreement with the Government no more beer (measured in standard barrels, 36 gall of specific gravity 1055) is produced each year than in the year ended Sept 30, 1939 The total bulk of beer produced ("bulk barrels") may be greater, but the amount of alcohol cannot rise above the 1939 figure Shortage of labour and of materials (especially malt and sugar), damage to plant by bombing, and problems of transport have made it difficult for even this output to be attained In some areas there has been an increased demand, on the other hand there are grounds for believing that the consumption of beer ell off notably in blitzed areas such as London Where there as been a local increase in demand it is attributable to the hift of population, longer hours of daylight (double summer ime), more money in wages, and fewer means of spending it n food and clothing

Other alcoholic drinks have become notoriously hard to get The output of whisky and gin for the home trade has been imited to half, and these drinks have become inordinately expensive, brandy and wines are becoming unobtainable Until the war the consumption of British manufactured wines made from imported grape juice had risen steadily from 2,841,977 gall in 1929–30 to 6,470,691 gall in 1938–39, but the tax on them has been increased considerably, and the source is no doubt nearly exhausted

Police-court statistics are informative about areas where drinking is excessive Figures are available for 82 out of 85 English and Welsh county boroughs, and for 22 out of the 66 counties There were 35,478 proceedings for drunkenness in the county boroughs in 1940, this meant a drop of 12% from the previous year There were 29,129 convictions—a drop of 9% from 1939 In the 22 counties proceedings and convictions for drunkenness had similarly diminished by 12% Part of the decrease in the county boroughs has been contributed to by London where the fall was notable

	1940	*1939*	*Decrease*
Proceedings	14,145	18 062	3917
Convictions	11,980	15 252	3272
Charges proved	13,806	17,600	3794

It would be a mistake to read much into these figures. the police had more important things to do than arresting drunks, and the population had lessened

The number of patients admitted to a London observation ward (Bow) for alcoholic psychosis in 1940–41 did not change appreciably from that of a normal peace year 1935–36 There is no evidence of increased drunkenness in the home counties, to which a part of the London population has moved The areas in which there has been the most striking decrease or increase in proceedings and convictions for drunkenness are given in table IV

ACCIDENTS

Road accidents have increased alarmingly. The Royal Society for the Prevention of Accidents attributes this not only to material factors such as shortage of traffic police, abnormal special traffic, and lighting restrictions, but also to psychological changes "mental preoccupation due to war strain, exasperation induced by transport difficulties and delays" and so forth The Parliamentary White Paper of Nov 21, 1941, says the same Between September and December, 1940, 4380 people were killed on the roads—245 more than in the corresponding months of 1939, and 1884 more than in the corresponding months of 1938 In the first 12 months of the war 8358 persons were killed on the roads, an increase of 25% over each of the years 1935–38 In the second 12 months of the war the number of deaths rose by a further 20% to 10,073 During May, 1941, 701 people died of road accidents, against 449 in May, 1940; for June the corresponding figures were 618, against 479 It is not possible to say how far mental stress has contributed to this enormous rise in road accidents, most of which occurred during the hours of daylight

It has been asserted that accidents in factories may be symptomatic of strain This is, however, not the main explanation of the rise in industrial accidents which occurred immediately after war broke out and has continued, during 1939 fatal accidents in factories increased by 17%, and in 1940 they were 25% higher than in 1939 When so many untrained youthful workers are being hurriedly absorbed into industry, a high accident-rate is to be expected Nevertheless, the possibility that the strain of war-time conditions with resultant fatigue and carelessness, acts as a contributory if minor cause of accidents cannot be eliminated More plainly relevant are reports on the health of factory workers In the Annual Report of the Chief Inspector of Factories for 1939 the senior medical inspector described conditions (possibly neurotic) of pallor, impaired digestion and lassitude which it was thought might have been due to the black-out strain produced by expectation of air-raids, anxiety, overwork, &c The Deputy Chief Inspector said in May, 1941, that a return from 5000 factories showed that nearly half of them were working over 56 but under 60 hours a week This is risky in the long run from the standpoint of mental and possibly of physical health, the 1916 Committee on the Health of Munition Workers spoke of the "state of reduced efficiency and lowered health" due to insufficient daily and weekly rest Adequate data are not available Absenteeism may also be a symptom of mental, or of physical, ill health, though the causes indicated in the 17th report of the Select Committee on National Expenditure—especially transport difficulties and longer working hours—are more common and important Some investigations have suggested, however, that the strain of poor sleep (through air-raids), anxiety, loss of home, and long hours of work followed by tiring travel play a large part in absenteeism in such badly blitzed towns as Plymouth or Bristol

CHILDREN

Observations on children have been chiefly directed towards the ill effects of separation from home and parents through evacuation, and the effects of air-raids, juvenile delinquency has excited public and official attention

In February, 1941, an investigation, of the questionnaire type, into 6000 Bristol school children after severe air raids, showed about 300 (4%) with symptoms of nervousness attributed to raids—anxiety, trembling, crying, enuresis, headache, sickness, dizziness Half the affected children were between the ages of 5 and 7, a third between 8 and 10, a quarter between 11 and 14 Later a survey was made of some Bristol children who had had to be removed hurriedly from a hospital when it was hit by a high explosive bomb, at the height of a severe air-raid Nearly two thirds of the children showed signs of stress for a period between 3 weeks and 2 months afterwards and 11% of them still showed persistent symptoms 7 months afterwards, but these did not occur in children over 5½ years of age Similar observations were made on other children in Bristol, and in Manchester, as well as on children evacuated to a Welsh seaside area after severe raids in these children the amount of nervous disturbance was dependent, apparently, on the amount of fear experienced by the child during the raid, frightened mothers communicated their fears to the children An investigation of children evacuated from London indicated that among 15,000 there were 420 cases of breakdown (2 8%) 249 were boys and 171 girls, most of them between 7 and 11, and their symptoms were enuresis, hysterical vomiting, sleep walking, fits, tics, anxiety and depression "Sometimes the symptoms, on arrival from a bombed area, were really acute for a few days One child had presented the complete picture of an adult depressive psychosis for nearly seven weeks" (This report is by a non-medical observer)

There is a consensus of opinion that children show great adaptability and recover well from air-raid effects, if simple, sensible measures are taken, likewise, that the strain of evacuation is great or little according to the care and success with which the foster home or billet is selected The carefully executed survey of London children evacuated to Cambridge demonstrates this, so far as the pre-blitz period is concerned An incidental examination of 656 school-children, reported in this survey, showed that 87 (13%) needed treatment because of mental ill health—36 were excessively anxious or depressed, 5 were self-absorbed, 36 abnormally quarrelsome and jealous, and 10 apathetic or delinquent

A great deal has been said in the newspapers and elsewhere about the increase in juvenile delinquency, which might be a sign of mental ill health In Manchester 1328 juveniles were prosecuted for indictable offences in 1940, compared with 746 in 1939 In Birmingham 1919 children (1720 boys, 199 girls) appeared on serious charges (e g , larceny, breaking and entering) before the Juvenile Courts during 1940, compared with 1433 in 1939 (1315 boys, 118 girls), and 1190 (1121 boys, 69 girls) in 1938 For the first quarter of 1941, however, there is a drop in Birmingham (351 boys and 49 girls, against 445 boys and 44 girls for the first quarter of 1940) The Home Office and Board of Education Circular (June, 1941) states that returns for the first twelve months of the war, compared with the previous twelve months, indicate an increase in the whole country of 41% in the number of children under 14 found guilty of indictable offences, and an increase of 22% in the age-group 14–17 The official circular points to the chief factors responsible for this The headmaster of a Liverpool school, author of a recent monograph on juvenile delinquency, writes

> “ In my own school there is no sign that the mental health of the children has been upset by bombing—and much serious damage has occurred in the immediate neighbourhood of the school Even those children (about a dozen) who have had their homes destroyed while they were either in them or in their shelter seem to be perfectly normal in their conduct
>
> I am satisfied that the increase in delinquency cannot be considered as symptomatic of neurosis The very fact that we were able to forecast the increase, and even, broadly, its amount, is an indication that other causes must be held responsible Lack of parental control is always the most potent cause of delinquency As a direct result of the war, much of the abject poverty found among certain classes has gone , but the conditions in which they live remain the same, or often worse when families have to find fresh accommodation In families where the father is now away from home there will often be a marked deterioration in control
>
> What I have said refers to children who have remained at home Many thousands of children, of course, are altogether away from the care of their parents, and not all are properly supervised in their billets This has provided further opportunity for delinquency Again, the police have less time to spare for the prevention and detection of crime In other words, the war has caused an all round relaxation of control, with the inevitable result that more children have got into trouble I have mentioned only a few points , many others such as the interruption to education and the shortage of men teachers could have been enlarged upon I am not prepared to say that ‘ greater laxity of external control under war conditions ’ is the sole cause of the increase in delinquency, but I am convinced that it is the chief one ”

It seems proper, therefore, to regard juvenile delinquency as a social malady, still remediable, rather than as evidence of mental ill health in individuals That is not to say that social ill health is immaterial from the standpoint of mental hygiene , psychopathic disorders of personality, tending towards neurosis, flourish in a bad social soil

DISCUSSION

The incidence of mental illness in the Fighting Services has not been dealt with here, though in so far as exposure to enemy attacks is concerned, soldiers in this country are in the same position as civilians Where they differ is in the circumstances of their daily life , the soldier is separated from his family and has very little say in the choice of his military job, and less independence in most respects than he had before Such social and emotional factors evidently play a larger part than exposure to danger in determining neurotic illness in soldiers while in this country The incidence is not high, but is higher than in the corresponding civilians, who have presumably found or made for themselves a milieu into which they fit The psychopathic soldiers who are discharged from the Army as unfit go to swell the ranks of neurotically ill persons in civilian life , they do not, as is sometimes suggested, lose their symptoms as soon as they have obtained their discharge Their subsequent industrial level, in a random sample of 60 whom I followed up, was lower than before they joined the Army, and they are in most cases unduly upset by air-raids

The analysis of causes for neurosis is notoriously misleading It is almost impossible to assign to the various stresses of war their relative importance in producing mental ill health Certainly, the terrors of an actual air-raid (against which the careful preparations of the Emergency Medical Service were directed, to avert panic and to treat sudden anxiety, stupor, or hysteria) have proved less important than the disruption of homes, and other secondary effects of bombing , and more important than air-raids are the great social alterations of the war (rearrangement of industry, evacuation) It is probable that a lowering of physical health, whether through epidemics or nutritional changes, would lead to a corresponding rise in the incidence of neurotic illness , they are very closely linked (Compare the London figures for “ neurotic symptoms ” and “ neurosis,” table III)

The mental effect of air-raids varies with local conditions London, sprawling and many-bodied, can suffer much damage without most of its citizens being personally and directly affected Plymouth or Coventry, more unified, small and concentrated, can be so devastated that every citizen is affected, and the interference with essential services—*food, warmth, light, water*—serves to intensify depressive and other neurotic reactions A non-medical observer (Harrisson 1941) has said that after raids on these towns there are cases of lethargy or stupor which are not seen by doctors , this has been questioned, but in any case his statement that an air raid means a more personal and upsetting threat to the inhabitants of a provincial city than to Londoners can be accepted, with some of its implications as regards neurosis

Attention to signs of impaired morale in the population concerns itself chiefly with the premonitory and early signs of neurosis, such as are shown by people who cannot talk of anything else but the bombs for weeks after a raid , paranoid people who suspect strangers of being spies , depressive pessimists who see no chance of their town reviving after all this destruction , anxious worriers about the imminence of the next raid The number of people showing such behaviour after a raid is unknown, but no-one has asserted that it is considerable, or that the unhealthy manifestations, when they occur, persist long

Investigation of all these matters is desirable since they affect public safety and public health, and the available data are scanty and in some respects discrepant Discretion and relevant experience would be essential in any field investigators The existing state of the law regarding compensation for neurotic disabilities indicates the danger , a woman was recently awarded £700 damages for hysteria and “ nervous shock ” sustained by merely witnessing a motor-car accident as she walked along the footpath If for “ motor accident ” could be substituted “ exploding bomb,” and for “ damages,” “ injury allowance ” or “ pension,” the situation would be serious, not only for the public exchequer but for the public health The inquiry could, however, safely and profitably be carried out by properly trained people aware of the pitfalls

SUMMARY

Air-raids have not been responsible for any striking increase in neurotic illness Crude figures from hospitals and outpatient clinics even suggest a considerable drop , the Ministry of Pensions figures, however, give a better indication of the problem

Reliable data from London and Bristol, and the impressions of good medical observers, indicate that after intensive raids there is a slight rise in the total amount of neurotic illness in the affected area, occurring chiefly in those who have been neurotically ill before Neurotic reactions may not show themselves for a week or ten days after the bombing , they usually clear up readily with rest and mild sedatives Hysteria is uncommon, anxiety and depression are the commonest forms of upset

The incidence of neurotic illness has been low in fire-ghters and other workers in civil defence

Insanity has not increased, so far as figures are to and, though more persons with senile deterioration have been admitted to mental institutions than before, because their relatives could not any longer look after hem or because the raids had in other ways disturbed heir routine and their precarious adaptation The same was true of some defectives

Suicide has diminished in Scotland, especially among he middle-aged and elderly Figures for England and Wales are not available

It is impossible to distinguish between neurotic illness due directly to air-raids and that which may follow such secondary troubles as disruption and loss of one's home, evacuation, difficulties in transport to and from work, or temporary loss of employment It is to the war as a whole, with its accumulated stresses, that people have had to adjust themselves, and signs of failure to do this can be taken as warning signals of neurosis An increase in alcoholism would be such a sign, there is no evidence that there has been any increase of this sort The rise in road and industrial accidents has been considerable, many causes are at work, the psychological ones among which have not been analysed There has similarly been a rise in juvenile delinquency this cannot be regarded as tantamount to a rise in juvenile neurosis, but it suggests that the same environmental factors are at work as conduce to neurosis

RADIOGRAPHY OF THE FEMORAL NECK

F P FITZGERALD
F R C S I
ORTHOPÆDIC SURGEON TO WELLHOUSE EMS HOSPITAL BARNET

K C CLARK
F S R
RADIOGRAPHER IN CHARGE OF THE ILFORD RADIOGRAPHIC TECHNICAL AND DEMONSTRATION DEPARTMENT

OPERATIONS on fractures of the femoral neck necessitate accurate, rapid and clear radiography A combined film holder and pelvic rest is here described which helps to achieve these essentials Usually lateral pictures of the neck of the femur are taken with the tube between the legs, and the film cassette held manually in the region of the iliac crest This arrangement has many disadvantages The film may not be held steadily, or at the correct angle, or in the same position for each exposure, the cassette has to be wrapped in a sterile towel, which causes delay, and finally there is danger of exposing the assistant to direct X rays The apparatus described here overcomes these disadvantages It has been in use for about 18 months and even though the cases in which it has been employed have been fibular grafts (lately the grafts have been reinforced by a single fin nail) the definition obtained has been satisfactory (fig 1) The idea is based on the technique employed with the curved cassette before it fell into abeyance, and on apparatus seen by one of us (K C C) in the Orthopædic Hospital at Copenhagen

The apparatus (fig 2) is an addition to the usual perineal bar and buttock rest It consists of a horizontal cassette holder, to which is attached a vertical curved film support The buttock rest and horizontal cassette holder are made from two pieces of five ply wood (15 by 13 in), which are fixed ¾ in apart by three small wooden stops, or distance pieces, which also ensure correct and rapid positioning of the cassette for the antero-posterior film The perineal upright, roughly hemispherical in cross section, is made from a solid wooden block 6 in high and 4 in wide at its base It is let into the horizontal platform close to one side, and surrounded on its curved surface by a piece of three ply wood, a slot ⅜ in wide is left between the block and the ply wood to take the special X ray film pack (fig 2) The block is bored to fit the perineal bar of a Hawley or other orthopædic table, and is lead covered to prevent X ray scatter

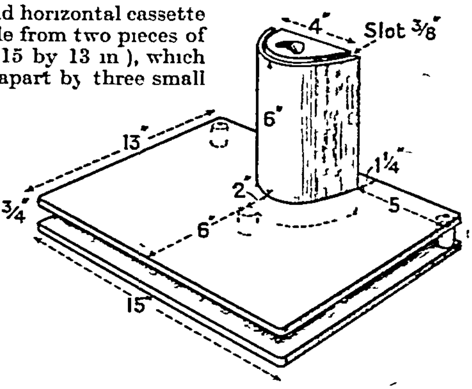

Fig 2—Horizontal cassette holder and vertical curved film support to fit over the perineal bar of the Hawley or other orthopædic table

TECHNIQUE

The ordinary pelvic rest and perineal bar of a Hawley table are fixed in position and the apparatus is fitted over the perineal bar The patient is adjusted so that the perineum fits closely to the upright (fig 3) The horizontal pieces are prevented from closing under the patient's weight by the central wooden stop A small X-ray film, 8½ by 6½ in, is used for the lateral exposure This has been previously prepared as follows

The film is placed between intensifying screens which are in turn inserted into a film envelope, the envelope is closed and with its contents forms a film pack which

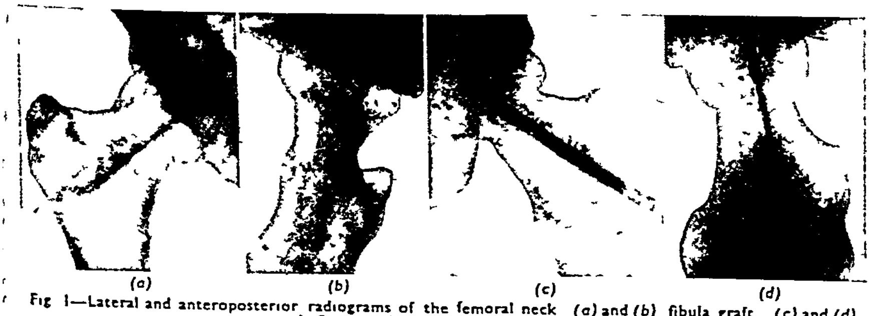

Fig 1—Lateral and anteroposterior radiograms of the femoral neck (a) and (b) fibula graft (c) and (d) a single fin central nail used to reinforce the graft

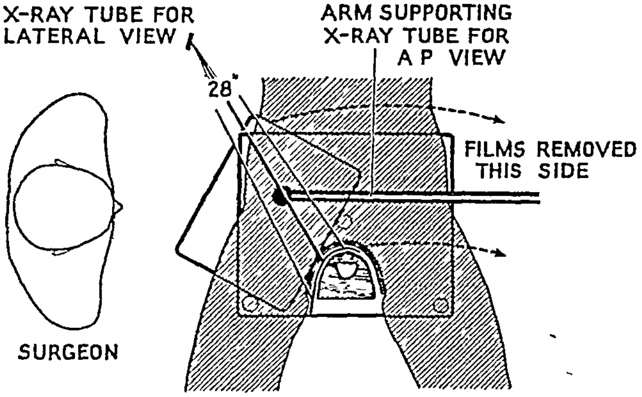

X-RAY TUBE FOR LATERAL VIEW
ARM SUPPORTING X-RAY TUBE FOR A P VIEW
28°
FILMS REMOVED THIS SIDE
SURGEON

Fig 3—Patient placed with perineum closely fitting upright anteroposterior and lateral films in position two X-ray tubes are in position and the direction of the X ray beam for the lateral view is indicated The films are removed from the side opposite to the surgeon

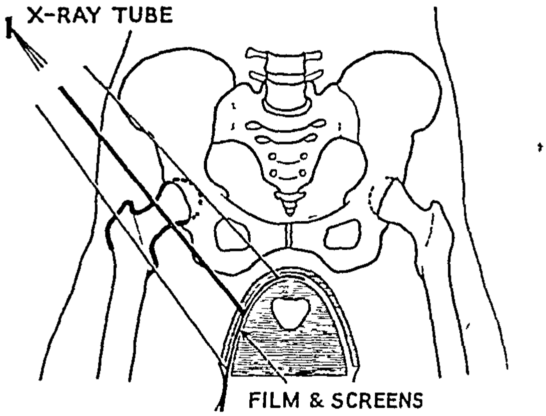

Fig 4—Film pack in position for the lateral view alignment between tube, neck of femur and film is indicated

replaces the usual metal cassette Special intensifying screens are available for this work, they are coated on a pliable celluloid base and do not crack when used without a cassette in the curved position

The film pack is gently curved to the shape of the perineal upright, before it is fixed in position between the block and its shield (fig 4), the correct alignment between film, neck of femur and tube direction is then readily obtained The two X-ray tubes are placed in position for the anteroposterior and lateral views, and they remain in this position throughout the operation When the lateral film has been exposed it can be removed from the *opposite* side to the surgeon and the cassette for the anteroposterior picture (10 by 8 in) inserted from this side Thus, the surgeon is not disturbed at any time during the operation

Rapid developer has been abandoned Instead ordinary developer and fixing solutions which have been heated to 90° F are used By this method an X-ray picture which is clear and permanent can be seen in 2 min. from the time the film is exposed (fig 1)

We wish to thank Mr S H Barr, radiographer at Wellhouse Hospital, and Mr A W Spain, clerk of works at the Royal Northern Hospital, for their assistance

DEVELOPMENT OF HYPOCHROMIC ANÆMIA DURING PREGNANCY

RESPONSE TO IRON THERAPY

H A HAMILTON
M B CAMB, M R C O G

HELEN PAYLING WRIGHT *
PH D LOND L M S S A

COUNTY HOSPITAL, FARNBOROUGH, KENT

IT is well known that physiological changes in blood-volume, and the demands of the fœtus on maternal iron reserves, render hypochromic anæmias especially frequent during pregnancy The characteristic decrease in hæmoglobin percentage, unaccompanied by a fall of the same degree in the red cells, makes the estimation of hæmoglobin the best guide to the adequacy of the woman's iron reserves The object of the present investigation has been to determine whether the current war-time dietary restrictions have had any detrimental effect on the hæmoglobin concentration of the blood of women during pregnancy The changes in hæmoglobin percentages have been followed and the results compared with others made on similar groups of cases before the war At the same time the effects of supplementing the diet with a medicinal preparation of iron have been examined

METHODS AND CLINICAL SOURCES

All hæmoglobin estimations in the present study were done by one of us (H P W) using the Haldane method (100% = 18 5 c cm O_2 capacity = 13 8 g Hb %) with a standard tube checked against that used by Price-Jones Estimations have as a rule been made once a month, but because regular intervals have not always been possible the hæmoglobin alterations during the period of attendance have been calculated as a weekly rate

The women attended the antenatal clinic of a hospital in the south-eastern suburbs of London between May, 1941, and March, 1942 The neighbourhood is classed as a "neutral" area, but air-raids were both frequent and severe there during 1939–40 Most of the women belonged to the upper artisan and lower middle class, very few could be considered as "poor" The majority were young primiparæ, though for this survey no distinction between nulliparous and multiparous women has been made The women usually attended the clinic for the first time between the third and fifth months of pregnancy and were examined monthly until the 25th week of gestation, thenceforward fortnightly until the last month, during which they were seen every week The clinical examinations (by H A H) were of the usual type—i e, blood-pressure, routine urinalysis and physical examination with X ray or further pathological investigations whenever considered desirable Apart from earlier estimations, every woman had her hæmoglobin estimated during the last month of pregnancy

The clinic was held on two days a week, and in order to control the results of treatment with iron all those women attending for the first time on one day were thenceforward given iron as ferri et ammon cit (gr 30 t d s) until delivery, except in a few cases where this preparation was ill tolerated when pil ferri sulph in the same dosage was administered Those who attended on the other day received no treatment with iron, whatever their initial or subsequent hæmoglobin percentages All cases in which the iron therapy was known not to have been followed have been omitted from this study

HÆMATOLOGICAL FINDINGS IN PREGNANT WOMEN WITH AND WITHOUT ADMINISTRATION OF IRON

—	GROUP 1	GROUP 2
	Treated (196 cases)	Untreated (196 cases)
Av initial Hb	75 % (10 25 g %)	79 % (11 0 g %)
Av terminal Hb	77 % (10 65 g %)	70 % (9 7 g %)
Proportion below 70 % Hb initially	24 5 %	9 2 %
Proportion below ,, ,, terminally	14 3 %	40 3 %
Proportion showing improvement (A)	54 %	13 %
Proportion showing no change (B)	9 %	6 %
Proportion showing deterioration (C)	37 %	81 %
Av weekly Hb increase in (A)	1 34 %	0 82 %
,, ,, ,, decrease in (C)	0 86 %	1 35 %

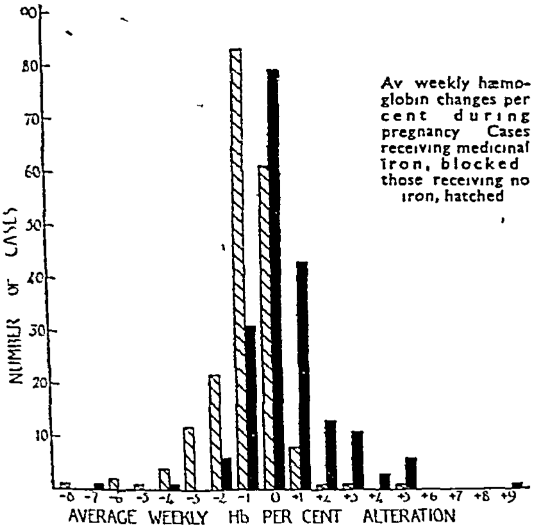
RESULTS

The results of the hæmoglobin estimations for the two groups of treated and untreated cases are set out in the first table The average hæmoglobin percentage on first attendance at the clinic was somewhat higher in the group of untreated women than in the treated group, although no selection had been exercised The hæmoglobin percentages at the end of pregnancy were, however, reversed—in those patients who received iron prophylactically it had increased while in those who were untreated it had decreased.

---

* Gillson scholar

In order better to show the effects of iron therapy, the two groups have been divided into three subgroups (A) those who improved, (B) those who remained unchanged, and (C) those whose hæmoglobin fell during the periods of observation. The proportions of cases falling into these subgroups are shown in the table. Of those receiving treatment, 54% showed an improvement, while of the untreated group 13% only improved. The extent of improvement in the two groups was also strikingly different, the average weekly rise in hæmoglobin in the treated cases being 1·34% (Haldane units), while that of the untreated case was 0·82%. Conversely, the proportions showing a decrease in hæmoglobin during pregnancy were 37% and 81% in the two groups. The average weekly falls in hæmoglobin in the subgroups (C) were considerably greater in the untreated than in the treated cases, this figure being 1·35% for the former and 0·86% for the latter. These differences for the two groups are statistically significant. The frequency distribution curves of the weekly hæmoglobin changes are shown in the figure.



Av weekly hæmoglobin changes per cent during pregnancy. Cases receiving medicinal iron, blocked; those receiving no iron, hatched.

There was a considerable difference in the proportions of the two groups initially falling below 70% hæmoglobin. In spite of the initial excess of such anæmic cases in the group receiving iron, an improvement occurred among these women so that at the end of pregnancy they were better than those who had received none. These latter had deteriorated so considerably that the very high proportion of 40·3% had hæmoglobin levels below 70%.

DISCUSSION

Reviewing the published work on the alterations in hæmoglobin percentages in normal pregnancies is difficult because of the many methods of estimation that have been employed. Often no description of the standard used has been given. Furthermore the period of pregnancy when the samples were examined is often not stated and, if repeated observations have been made, the intervals between the examinations are often omitted. For these reasons, and because of the discrepancies between American and British figures for "normal" hæmoglobin percentages (Price-Jones, Dill and Wright 1931), little attempt has been made to compare the present figures with those reported for pregnant women in other countries. The differences between this series of cases and those reported by other workers in this country shortly before the war may, however, be discussed.

It is now well established that the hæmoglobin percentages of women fall during pregnancy owing to a relative increase in plasma (see Dieckmann and Wegner 1934, Evans 1937), but observers agree that an anæmia of the hypochromic type is often superimposed (Bethell, 1936). Dieckmann and Wegner (1934) and Watson (1938) think that hæmoglobin levels below 10 g. % (72% Haldane) should be regarded as unphysiological. In this country these figures are usually accepted and cases falling below 70% have been regarded as anæmic (Davidson et al., 1935, MacKay 1935, Reid and Mackintosh 1937).

It has been found that the average initial hæmoglobin of 77% for the entire series is lower than the Aberdeen figures collected in 1935. They were not, however, so low as that found by Fullerton (1936) in his group of pregnant women having a weekly family income of less than 15*s.* per head, who had an average hæmoglobin of 73%. The terminal figure of 70% found for the group of untreated cases in the present series falls below that of Fullerton's group although their economic status was superior to that of the women he examined. MacKay's (1935) group of pregnant women were probably economically intermediate between Fullerton's and the present series. She found an average hæmoglobin of 83·5%, a figure far higher than that for the present series.

When the criterion of a hæmoglobin level below 70% is taken as the lower limit of normality, 16% of the entire series fell initially below this figure. This is only slightly better than that for the Aberdeen group of 17·5% and that for Fullerton's first group (less than 15*s* per head weekly), 19·5% of whom fell below this level. The present series is worse than Fullerton's second group of women with over 15*s* per head of family weekly, 14·3% of whom fell below this standard, while of MacKay's series only 4·6% had hæmoglobins below 70%. The proportion falling below 70% hæmoglobin at the end of pregnancy in the untreated group in the present series is considerably greater than any hitherto recorded, 40·3% showing such pronounced anæmias.

In the group of treated cases the terminal hæmoglobin concentration in the women's blood may be regarded as satisfactory. Even allowing that patients attending clinics sometimes take medicinal preparations irregularly, especially if these are unpalatable, the average hæmoglobin percentage rose during the period of observation, while the numbers falling below 70% hæmoglobin declined from 24·5% to 14·3%. The fall in the subgroup (C) was slight and within physiological limits. This transforming of a fall into a rise of hæmoglobin level in pregnancy in women treated with iron supports the findings of other workers (Galloway 1929, Toland 1936, Corrigan and Strauss 1936, Gottlieb and Strean 1939, Widdowson 1939).

No single factor has been found to account for the low levels of hæmoglobin percentages in the present series. The women when first seen already had hæmoglobins lower than is usual at that stage of pregnancy, so it is probable that they started their pregnancy with some degree of anæmia which became progressively worse. Though in some instances they complained of fatigue, giddiness or breathlessness, they were generally surprisingly well and able to continue their normal occupations. Financially their conditions had altered comparatively little since the beginning of the war, the chief changes having been brought about by the rationing of foodstuffs. Strauss and Castle (1933) found that anæmia developed during pregnancy if there were dietary or digestive disturbances, while Reid and Macintosh (1937) observed that the poorer the financial condition of the women examined the lower the hæmoglobin percentages tended to be. Davidson and his colleagues (1933, 1935) pointed out that the diets of low paid and unemployed workers were deficient in iron. It appears likely, therefore, that at the present time the condition of these pregnant women simulates that found ordinarily in women of lower financial status and that diets containing insufficient iron are more frequently taken than in normal times. It is important that milk is the only supplementary food allowed to women during pregnancy and that this contains no iron, so cannot combat the development of nutritional iron deficiency anæmias.

It appears from the figures obtained for this series, which may be taken as a fair sample of the pregnant women in the artisan population of the country, that the present condition of their blood is unsatisfactory and considerably worse than before the outbreak of war. Two main methods of overcoming the development of hypochromic anæmias appear to be possible. First, the administration of therapeutic iron preparations in adequate dosage should find a routine place in antenatal treatment Secondly, training in simple dietetics at the clinic centres might be organised to help the women to choose foods rich in iron and to prepare them in the most appetising manner

SUMMARY

Repeated hæmoglobin estimations by the Haldane method have been carried out on 392 pregnant women from about the third month of gestation until term

Half of the women examined were treated with medicinal iron throughout the period of observation, while the rest had no such medication

The average initial hæmoglobin percentages were 79 in the untreated and 75 in the treated group The corresponding average terminal percentages were 70 and 77, so that iron administration converted a deterioration during pregnancy into an improvement

From comparison with other published figures it is concluded that women of the artisan class are more anæmic than before the war

Iron preparations should be given as a routine during pregnancy and antenatal clinics should help expectant mothers to select and prepare iron-rich diets

We wish to express our thanks to Dr Constant Ponder medical officer of health for the county of Kent, for facilities afforded in connexion with these investigations

Medical Societies

DRIED FOODS

The Nutrition Society held its sixth meeting (fourth of the English group) on July 25 in conjunction with the Food Group of the Society of Chemical Industry, the subject being Dehydration of Foods and its Effect on their Nutritional Value The work reported was carried out mainly under the Food Investigation Board of the Department of Scientific and Industrial Research, and Sir **Edward Appleton**, secretary of that department, took the chair at the morning session The advances made in the study of drying foods were, he said, the result of excellent collaboration between the Low Temperature Research Station at Cambridge and the Torry Research Station at Aberdeen, which studied the technical methods of drying, and the Dunn Nutritional Laboratory at Cambridge at which the nutritional value of the foods was determined Much help had also been forthcoming from industry The function of scientists in war-time was not only to satisfy particular needs of Service or civil departments but also to anticipate likely needs The drying of foods, the study of which was taken up by the Food Investigation Board under the chairmanship of Sir **Joseph Barcroft** soon after the outbreak of war, was an example of such anticipation It had been calculated that some three million tons of water were imported annually with our food, so that drying could affect considerable saving in transport, labour and storage Dried foods have been known for a long time but have always been considered much inferior to fresh foods This was rightly so, for little study had been made of the best way to preserve their palatability and nutritional qualities But the progress made in the last few years was bringing us closer to one of our most important aims the provision of the best food for the United Kingdom and our Allies and ultimately the whole world

Mr **Franklin Kidd**, DSc (Low Temperature Research Station), in a paper on the principles and practice of food dehydration, stressed the differences between the old and the new methods of drying Until recently, dried foods were definitely a second best The extension of food preservation just before the war was mainly in the form of refrigeration This was really a form of drying, in that the water, being converted into ice crystals, was in effect removed from the food An elaboration of this was vacuum ice-drying, in which the ice crystals in the frozen food were evaporated off without thawing This process proved very successful but its development in war-time was impracticable, because the bulk of the food was not reduced and manufacture of the requisite industrial plant would have involved much time and labour Further work was therefore confined to the study of other methods of drying and there had emerged several general principles which guide the preparation of satisfactory dried foods For example a preliminary heat treatment is necessary to inactivate the enzymes which will otherwise cause deterioration of the food The final product should be kept in a dry atmosphere, oxidation can be guarded against by the exclusion of air and of catalysts such as metals and by the addition of antoxidants such as sulphite But no method of preparation can produce dried food of good quality from fresh food of poor quality Dr Kidd gave some examples of the saving effected by drying Dried carrots are $\frac{1}{12}$ of the weight and $\frac{1}{18}$ of the volume of fresh carrots Not all foods show this amount of saving but a complete week's ration could be produced whose weight and volume would be about a quarter of that of the equivalent fresh food

MEAT, EGGS AND FISH

Mr E C **Bate-Smith**, PhD (LTRS), read a paper on dried meat and eggs, written in collaboration with Mrs E M Cruickshank, PhD (Dunn Nutritional Laboratory) and Mr J G Sharp, PhD (LTRS) Meat and eggs are valuable mainly for their protein and caloric value rather than for their vitamin content and they also provide highly palatable constituents of the diet In the preparation of these dried foods they were therefore guided mainly by the criterion of palatability, but it was found that the conditions which best preserved this were also those which least affected their nutritive value The best method for meat was found to be the air drying of the coarsely minced meat at about 60° C, and by this method the digestibility and biological value were as good as those of cooked fresh meat Rotary steam drying in a vacuum was also effective provided the temperature was not allowed to rise too much Temperatures above 80° C, for example, destroyed some of the vitamin B_1, and commercial rotary driers destroyed all of it Preliminary work on nicotinic acid and riboflavin indicated that these are also unaffected at the lower temperatures With eggs, it is important to retain the power of reconstitution and only air drying can do this Here too, if the temperature is kept low, as in spray drying, no deterioration of palatability or nutritive quality occurs, on the other hand, band drying, in which low temperatures are also used, results in loss of some of the vitamin activity owing to the lengthiness of the process The palatability of many samples of both meat and eggs have been tested by panels in several parts of the country, and products agreed to be highly palatable are now relatively easy to obtain

Mr G A **Reay**, PhD (Torry Research Station), spoke on the drying of fish Although drying, with or without salting, has been carried out for centuries, this is always accompanied by considerable changes in flavour and palatability Modern methods, which so far have been confined to the drying of lean fish, have produced fish which compare favourably in quality with fresh fish The fish is first cooked and then either roller dried, or better, air-dried on trays The dried product reconstitutes very well and tastes nice Its volume is $\frac{1}{8}$ to $\frac{1}{10}$, and its weight $\frac{1}{6}$ to $\frac{1}{8}$ that of fresh fish As a rule it keeps well but some samples have deteriorated after a few months The problem of storage clearly requires further work

Mr **Nevill Wright** FIC, of New Zealand, appealed for a pooling of the mass of knowledge which must have been gathered by those working on the problems of food drying in many countries —Dr A S CFARLANE

Lister Institute) agreed with Dr Kidd that suspension f the method of vacuum ice-drying during war-time was easonable but emphasised two advantages of this process First products prepared by this means can be reconstituted on the whole better than those prepared by other means, especially is this so with milk and fruit juices Secondly, they have a smaller surface area than, for example, spray-dried foods and consequently are less liable to oxidation Mr D H F CLAYSON, BSc, urged the importance n these days of fuel economy of studying the relative efficiency of various types of drying apparatus —Mr C E SPOONER, MScTech, said that the drying efficiency of many methods now used is in fact very good He suggested that the replacement of oxygen in the storage containers by an inert gas such as nitrogen might improve the keeping qualities of the products —Mr R T COLGATE, DSc, thought that the preparation of dried eggs presented problems similar to those encountered in the preparation of wheat gluten, of which he had had experience This substance preserves its aerating qualities much better when vacuum dried than when dried in the air, the same is probably true of eggs

In their replies Dr KIDD said that experiments are being done on the effect of storing the dried products in inert gases and Dr BATE-SMITH assured Mr Clayson that the question of fuel consumption in the drying process is being studied, though this represents only a small fraction of the total cost of preparation

VEGETABLES

At the afternoon session, with Mr H E COX DSc chairman of the Food Group, in the chair a paper by Mr R J L Allen, PhD Mr J Barker PhD (LTRS), and Mr L W Mapson, PhD (DNL) on dried vegetables was read by Dr ALLEN The three desiderata are retention of colour, retention of maximal nutritive properties and preservation of both during storage Taking cabbage as an example, the procedure is to cut the trimmed cabbage into thick shreds and scald for 2 or 3 minutes in water containing a little sulphite The scalding reduces the quantity of vitamin C but this effect can be minimised by reducing as much as possible the volume of the solution and the time of scalding and by using the same solution for repeated scalds By this means cabbage can be dried so as to contain 70–80% of its original vitamin C If it is then cooked as recommended it will retain some 35% of its vitamin C, a figure which compares favourably with the amount left in the cooked fresh vegetable Carrots and potatoes have also been successfully dried, the process differing only in detail from that used with cabbage Carrots are scalded whole and then sliced With potatoes it is necessary to choose suitable varieties and avoid the presence of iron in order to prevent blackening of the final product These dried vegetables keep well in storage for at least a year

Mr V L S CHARLEY, BSc (Long Ashton Research Station), considered that one of the most important results of these new methods of food preservation would be that vegetables, now grown in such quantity would be saved from wastage, they could then be distributed in the two or three months when there is a shortage He wondered what the attitude of the Ministry of Health would be to the presence of sulphur dioxide in these products and also questioned the need for so much waste in preparing the vegetables before drying he understood that as much as 50% of cabbage and 20% of carrots are so wasted Could not the scalding water, with its vitamin C and mineral salts, be incorporated in some way in the final product ?—Mr T RENDLE, FIC, referred to the commercial preparation of these dried products A considerable amount of work has already been done with pilot plant and a start has been made with plant for large-scale production —Mr B G MCLELLAN, MIChemI, suggested that those concerned in the drying of foodstuffs should get in touch with engineers who would be willing to cooperate fully in the development of methods of large-scale food production It would be of great benefit if the plant were erected in the growing areas and also if small-scale plant could be made available to deal with surplus vegetables from gardens and allotments

Dr ALLEN, in reply, said that with some varieties of cabbage the wastage is much less than 50% and in fact parts ordinarily discarded can often be incorporated in the preparation they may indeed improve both its colour and nutritive value Most of the SO_2 used in the process is eliminated during the later stages of preparation It is difficult to incorporate the water used for scalding because of the high amounts of SO_2 in this —Dr MAPSON, who was responsible for the nutritional part of the investigation described by Dr Allen, pointed out that the principles discovered in this work could readily be applied in domestic working, for example, preservation of the vitamin C by cooking in water in which the inedible vitamin-rich portions had just been boiled In some respects it is easier to preserve this vitamin in the dried vegetables, since bruising and enzyme action which causes loss in fresh vegetables do not occur with the dried products Loss after cooking due to oxidation of the vitamin when the cooked vegetables are kept hot will occur equally with either type, but the ease with which the dried vegetables can be reconstituted and cooked may eliminate the need for the use of the hot plate in canteens

UTILISATION

The last paper of the day, on the utilisation of dried foods was read by SIR JOSEPH BARCROFT Previous speakers had stressed the advantages of the new processes in storage, ease of cooking and so on but he felt that quality was of equal if not greater importance The adoption of drying means that a greater proportion of people will have easily available foods of high quality Some food suppliers may think these products offer unfair competition but only "fresh" foods of poor quality—stale fish and stale milk—will be affected The process of drying has of course other advantages an important one is the avoidance of wasting foods during periods of high production or gluts Seasonal gluts, such as the high yield of milk in early summer, will be easier to deal with than the unpredictable gluts of an exceptionally good yield but even these could be dealt with at any rate partially, by appropriate organisation. Ease of cooking anther feature of dried foods, would considerably affect not only cooking in canteens but also domestic cooking

Squadron-Leader T F MACRAE PhD, spoke of the use of dried foods in RAF canteens They are popular with cooks, catering officers and medical officers They supply a variety of palatable foods which it is otherwise not always possible to obtain and considerably reduce the time and trouble of preparation Tests have shown that meals prepared from dried vegetables provide about twice as much vitamin C as those prepared from fresh vegetables, mainly owing to the difference in the losses during cooking In palatability tests dried cabbage, for example, was taken at least as well as the fresh vegetable

Mr J HAMMOND DSc, FRS (Cambridge School of Agriculture), said that dried foods would affect production, distribution and storage, and consumption Production would be affected by the fact that they would make it possible to deal with gluts There are parts of the world, such as Rhodesia and Northern Australia, which might produce large amounts of meat but which at present cannot be exploited owing to the difficulty of feeding workpeople in these areas this could be overcome by supplying workers with dried foods Dried foods would make distribution much easier and cheaper, they should greatly lessen the difficulties of postwar relief The fact that dried foods can be stored and readily transported means that there can be a more uniform supply of foods throughout the year for people of moderate means

* * *

The meeting did not deal entirely with these theoretical aspects of drying foods Demonstrations showed how rapidly dried cabbage and potatoes could be reconstituted, and samples of dried foods, both as stored and as prepared for eating were on view Minced meat and fishcakes, with cabbage potatoes and carrots were there for members to taste and the general opinion was that it was impossible to guess that they were not ordinary fresh foods

M Maisky the Soviet ambassador to this country, has given £100 to the Anglo Soviet Medical Council for their future work

Reviews of Books

After-Treatment

H J ATKINS, D M, M Ch Oxfd, F R C S, assistant surgeon to Guy's Hospital, London Oxford Blackwell Pp 266 15*s*

THIS guide for all doctors and nurses who have the care of patients after operations is the more valuable for its emphasis on the human side of treatment and the common-sense approach to problems of convalescence The size is just right, it is not overburdened with unpractical discussions, and the advice given is sound and simply expressed There is little to criticise, but if Mr Atkins would consult Murphy's original writings on the rectal administration of water, he might alter the views expressed on p 11 The rectum should never be called upon to accommodate 5 pints of saline, nor can the surgeon do anything to influence the absorption by the rectal and colonic mucosa, yet if fluid is given by the original method 7–8 pints may be absorbed in comfort by a dehydrated person Surgical opinion is veering away from soaks for septic fingers though there is much to be said for them There is no need to use the noisy Sprengel pump for keeping a patient with a suprapubic opening dry the old-fashioned simple gravity suction pump is as effective Hexamine, recommended as a urinary antiseptic, has been discarded by most urologists The direction to use "half-strength hamamelis solution" for stopping vesical hæmorrhage is ambiguous, and an unusually gloomy picture is presented of the result of hydrocele operations Care of a colostomy is extremely well and carefully detailed The appendices advise about report-writing and the giving of evidence in a court of law The book is one of the best and most attractive on a subject often insufficiently mastered by the newly qualified doctor

Lymphatics, Lymph and Lymphoid Tissue

Their Physiological and Clinical Significance CECIL KENT DRINKER, M D, D Sc, professor of physiology, school of public health, Harvard University, JOSEPH MENDEL YOFFEY, M D, F R C S, senior lecturer in anatomy, University College of South Wales, Cardiff London Humphrey Milford, Oxford University Press Pp 406 22*s* 6*d*

THE physiology of the extravascular circulation and the lymphatic system continues to fascinate experimental physiologists This well-illustrated volume, which is the second Harvard University monograph in medicine and public health, reviews the structure and the experimental and applied physiology of the lymphatic system in mammals Neither physiologist nor clinician will find it too technical The mechanism and control of capillary permeability and the composition of the tissue fluids are considered in detail, and they have never been of greater general interest than in these days of universal chemotherapy with the sulphonamide compounds The influence of the lymphatic system on the spread and control of bacterial and virus diseases and the mechanism by which particles and bacteria gain access to the tissues and lymphatics of mucous and serous membranes are fully discussed, and other topics critically considered are the embryology and evolution of the lymphatic apparatus, the characters of lymphocytes (which incidentally move faster than leucocytes), the relationship of lymphocytes to other cells, the influence of various forms of physiotherapy on the circulation of lymph and, therefore, on the general circulation, and the rôle of the lymphatic apparatus in circulatory disorders such as hypertension, nephrosis, acute inflammation and surgical shock Those who wish to pursue the subject beyond the confines of this book will find the abundant bibliography an asset

Surgery of Modern Warfare

(2nd ed) Editor HAMILTON BAILEY, F R C S Edinburgh E and S Livingstone Vol I Pp 480 40*s*

THE re-issue in two volumes of this now well-known work has given its editor the opportunity of some regrouping The first volume before us is concerned with wounds in general, and with those of the blood-vessels, head, face, spine, chest and abdomen in particular Lack of balance between the various sections has not been entirely adjusted, 30 pages are devoted to the exposure of the main vessels of the limbs—a subject more suited to a book on surgical anatomy—whereas wounds of the thorax are dealt with (albeit admirably) in 20 The sections on injuries of the brain and skull by Mr Norman Dott and on wounds of the face and jaws by Mr Pomfret Kilner are among the best in the book, and both are beautifully illustrated At present, when many young surgeons are being called on to carry out operative work of a type in which they have had little experience, this book will prove a welcome guide

Surgery of Head and Neck

ARTHUR S MCQUILLAN, M D, F A C S, clinical professor of surgery, New York University Medical College London Humphrey Milford, Oxford University Press (Medical Outline Series) Pp 138 12*s* 6*d*

THIS book covers general surgery in outline In his preface, Professor McQuillan states his wish that it may "prove worth while as an aid to the undergraduate student, the interne and the practising surgeon" We feel doubtful about the value of any sort of medical outline for the student, who should gradually attain knowledge of his subject and not stuff himself with facts and figures No stress is laid on general principles, even in the discussion of tuberculous disease of the cervical spine But for the hospital resident and practising surgeon the book may serve a useful purpose despite the excessive, and not always orderly, tabulation. The general arrangement is satisfactory and on the whole the facts given are reliable and up to date, although epulis is listed among malignant tumours of the gums and jaws, and under brachial plexus injuries only the lower-arm type of paralysis is mentioned

Pediatric Gynecology

GOODRICH C SCHAUFFLER, M D, assistant clinical professor of obstetrics and gynecology, University of Oregon medical school Chicago Year Book Publishers, London H K Lewis Pp 384 27*s* 6*d*

THIS well-illustrated book is, as Professor Schauffler claims, a pioneer work on subjects which have apparently never been grouped together before He does not aim at being exhaustive on all diseases peculiar to the female child, but has selected those which in his experience and that of his colleagues present special difficulties in diagnosis and treatment Pyelitis and enuresis are discussed fully and British urologists will welcome the observation that minor developmental abnormalities are often found associated with recurrent attacks of pyelitis He considers that only 5–10% of enuretic patients can be shown to have an organic lesion The ætiology, diagnosis and treatment of pelvic peritonitis are thoroughly discussed and a section on the vexed question of vulvovaginitis deals fully with treatment It seems that American workers have been disappointed with sulphonamides given by mouth Endocrine deficiency and associated genital undevelopment are discussed and should stimulate research in a field that has hitherto been somewhat neglected here The last chapter, on the social service aspects of pædiatric gynæcology, deals with the practice of American law, but its principles are of wider application

Sanitary Inspector's Handbook

(5th ed) HENRY H CLAY, F R San I, F I S E, major R A M C London H K Lewis Pp 534 18*s*

THE original sanitary inspectors were inspectors of nuisances, their work was not specialised and they were generally untrained Later they became lay assistants to medical officers of health to do what they were told to do without needing much special erudition The advance of public health led to their work becoming highly specialised, partly divorced from that of other technicians in the service, and calling for experts of a new type, highly trained and capable of bearing responsibility Textbooks were therefore needed by students for the qualifying examination, by practitioners for reference The need was poorly filled until Mr Henry Clay brought out his handbook in 1933, it was a big book and has increased in size with each edition, but it contains nothing superfluous What is to be known is put concisely by an expert of long and varied experience who is an examiner of standing and whose writing is neither vague nor dictatorial The popularity of Clay is therefore not surprising

THE LANCET

LONDON SATURDAY, AUGUST 15, 1942

PRACTITIONER AND PATHOLOGIST

The medical student spends a good deal of time in learning how laboratory examinations of the blood, tissues and body-secretions help in the diagnosis of disease When he goes into practice, he soon discovers that if he wants laboratory tests done he must either call out an expensive consultant or send his patient to the outpatient department of a hospital, whence, too often, there is no return True he may send throat-swab or sputum or even blood and fæces to the public-health laboratory for help in the diagnosis of infectious diseases like diphtheria, tuberculosis and typhoid, but these infections form a small part of his practice, and so the practitioner soon forgets much of what he had learned about laboratory aids to diagnosis What he needs is a diagnostic centre to which he can send or take his patient for a blood-count, gastric analysis or renal-function test, and where he himself can get expert advice from the pathologist for a nominal fee In this way he keeps his patient, and learns much medicine A service along these lines has for some time been working satisfactorily in Kent where the cost of the laboratory work is a charge on the county rate [1]

In hospital the clinician, from houseman to honorary, is too apt to regard the pathologist as the servant of his craft, and to demand of him all manner of tests which may or may not be essential to diagnosis or treatment This overdependence on the ancillary aids to diagnosis—and the X-ray department suffers as much as the laboratory—may, if carried too far, lead to a decay in the practice of sound clinical medicine which attempts first to establish the diagnosis by interrogation, observation and physical examination Perhaps the clinician is not sufficiently versed in the uses and significance of modern laboratory tests [2], he must not cloak his ignorance by asking for a whole series of examinations which may add little to diagnosis and will certainly absorb much time and energy in the laboratory Closer liaison is needed between the ward and the laboratory, with more frequent bedside and telephone discussions between clinician and pathologist about the nature of the case and the laboratory tests which are most likely to be helpful The pathologist naturally gets exasperated if the clinician regards the laboratory merely as a machine for turning out reports And now that increasing shortage of staff means curtailment of work it is more important still to eliminate unessential tests Examples of the avoidable are complete blood-counts on patients with no clinical signs of anæmia in case of doubt a simple hæmoglobin estimation is enough Blood-sugar curves are not required—but are often requested—in confirmed diabetes Fractional test meals are seldom necessary examination of the fasting juice after a charcoal biscuit the previous evening will usually give all the needed information Another grievance is that patients who are readmitted or transferred to another hospital must have a new set of laboratory tests done when the telephone or a polite note would elicit the collected data without further trouble to patient or pathologist Housemen have to pander to the foibles of the honorary, and on the day before the big visit they flood the laboratory with requests for examinations which might "interest the Chief," but will add nothing positive to the diagnosis

Let it be more widely recognised that the pathologist is not a technician but is as a rule a man with a wide and accurate knowledge of medicine which he is glad to put at the disposal of his clinical colleagues Let there be an end to the spirit of armed neutrality which sometimes exists between ward and laboratory and let us have in its place a friendly partnership which will bring benefit all round Such a partnership can best be achieved by including a period of laboratory work in the training of the resident medical officer, so that later on he will properly appreciate the place and function of clinical pathology vis-à-vis clinical medicine In this we can learn much from our American cousins

---

[2] If so he should read Biochemistry of Disease" by Meyer and Oscar Bodansky New York and London Macmillan 1940 Pp 684

PENICILLIN PURIFIED

In the last two years Chain, Florey and their colleagues [1] [2] in Oxford demonstrated that a partially purified preparation of penicillin, a substance first produced from the mould *Penicillium notatum* by Fleming [3] in 1929, possesses remarkable antibacterial activity against certain organisms and with its low toxicity has therapeutic possibilities The penicillin preparation first used for therapeutic trials on man inhibited the growth of a number of gram-positive bacteria at a dilution of 1 1,000,000 Yet it could be injected intravenously into mice in substantial doses without producing ill effects and could be successfully given by the same route in the treatment of bacterial infections in man A considerable further purification of penicillin has now been reported by Abraham and Chain [4] and the biological properties of the new product have been studied by Florey and Jennings [5] Its antibacterial activity is much greater than that previously obtained, the new preparation inhibiting the growth of staphylococci completely at the astonishing dilution of 1 25,000,000 and partially at a dilution of 1 160,000,000 Other gram-positive bacteria, though not tested with the purest penicillin, which is scarce, are also inhibited at high dilutions As Fleming showed, the gram-negative organisms are less sensitive to penicillin than the gram-positive ones However, a preparation of penicillin only half as pure as the best obtained has been found to inhibit the growth of *Salmonella typhi* and *S gaertneri* at a dilution of 1 30,000 and to have some effect at 1 120,000 Toxicity might have been expected to increase with antibacterial activity, but in fact the toxicity of the highly purified preparation is less than that of the earlier partially purified ones A dose of 20 mg of a penicillin preparation with half the antibacterial activity of the purest obtained had no apparent effect when injected intravenously into a 20 gramme mouse

---

[1] Chain E, Florey, H W, Gardner A D Heatley, N G, Jennings, M A, Orr Ewing, J and Sanders, A G *Lancet*, 1940, ii, 226

[2] Abraham, E P et al *Ibid* 1941, ii 177

[3] Fleming, A *Brit J exp Path* 1929 10, 226

[4] Abraham, E P and Chain, E *Ibid*, 1942 23, 103

[5] Florey, H W and Jennings, M A *Ibid*, p 120

This is a dose of at least 5000 " Oxford units," [6] and the effective therapeutic dose used in experiments on mice was 5–10 units subcutaneously at three-hourly intervals These figures give some idea of the great latitude between an effective therapeutic dose and one which a mouse will tolerate without toxic symptoms A dose of 10,000 units in the form of a much cruder preparation given to a man produced well-marked bacterial inhibition in his blood for at least an hour Other evidence of low toxicity was that human polymorph leucocytes survived for an hour in a 1% solution of purified material In view of the very low toxicity of penicillin it may be possible to maintain concentrations in the tissues which will bring at least some of the gram-negative organisms within its therapeutic reach

Purified penicillin is a chemotherapeutic agent even more remarkable than the studies of the partially purified product foreshadowed It is almost equally active against many gram-positive organisms It is many hundred times as active as the sulphonamides and at the same time less toxic than the least toxic of those drugs Its antibacterial activity is not affected by tissue constituents, or within wide limits by the number of bacteria present It has been shown to be active against sulphonamide-resistant streptococci,[5] a property which promises to be of great value Lately a number of antibacterial substances of various chemical constitutions have been isolated from fungi and bacteria (gramicidin and tyrocidin,[7] actinomycin,[8] citrinin,[9] penicillic acid,[10] streptothricin,[11] gliotoxin,[12] proactinomycin [13]) The available evidence suggests that these substances will prove to be many times more toxic than penicillin and it remains to be seen whether any of them will stand the test as clinical chemotherapeutic agents

Though penicillin has been purified to a high degree **Abraham** and **Chain** have not yet obtained it in a crystalline form, and it is therefore not certain that their purest preparation possesses the highest possible degree of purity From the analytical figures of the purest penicillin preparation, formulæ such as $C_{21}H_{32}O_{10}N_2Ba$ and $C_{23}H_{30}O_9N_2Ba$ have been suggested [14] The nitrogen content of penicillin is remarkable since nearly all substances hitherto isolated from fungi have been nitrogen-free The tentative formulæ of penicillin, with data obtained by spectrophotometric analysis,[15] suggest that several condensed hydroaromatic ring systems are present in the molecule Obviously penicillin is a complex molecule, and its instability towards acids, alkalis, heavy metals and many other chemical reagents makes the task of elucidating its chemical structure more than usually difficult, so that the prospect of synthesis still seems remote For the time being at least it will be necessary to rely on production by the mould, but in view of its potentialities methods for producing penicillin on a large scale should be developed as quickly as possible

PÆDIATRIC PLANNING

Among the 21 classical references to the child, thought to be worthy of inclusion in *Familiar Quotations*, there is only one which relates him to the adult—Wordsworth's " The Child is father of the Man " He may be curious or simple (Wordsworth again), or naked (Wm Jones), or happy (Ann Taylor), or tired (Shelley), or thankless (King Lear) He may be the object of yearning (King John), or of prayer (Longfellow), the embodiment of misery (Langhorne), or of suffering (Holmes) He may have a heart appropriate to the last roll-call (The Newcomes) and a speech remembered by St Paul, but it has been left to medicine to regard him as only a smaller edition of his parents and showing the same morbidities in lesser degree In London there is no professorial chair of pædiatrics and in the last prewar year seven provincial universities only allotted 5½*d* out of each £100 of their grant money to the special teaching of child health But a new outlook dates from the foundation in 1928 of the British Pædiatric Association, and at its fourteenth annual meeting held at Windermere in May under the presidency of Prof L G **Parsons** the more recondite problems of disease in childhood were laid aside in favour of a wide discussion of pædiatric planning This association of consulting pædiatricians and university teachers of pædiatrics in the British Isles has developed from an academic club into an advisory and executive body willing to bear the increasing responsibilities facing it

Conference turned on three main branches of pædiatrics domestic practice, public pædiatric services (such as child welfare and school medical services), and the hospital and institutional treatment of children After the war domestic practice will presumably remain largely in the hands of general practitioners or members of group practices specially interested and trained in children's diseases Obviously therefore the standard of undergraduate training in pædiatrics should be raised, encouragement being given by the simple expedient of questions at the final professional examination, and/or a period of postgraduate service in a children's unit required of all who aspire to treat the young The establishment of university centres, adequately staffed with both whole-time and part time pædiatricians, is the logical means not only of raising the general level of pædiatric education, but of providing consulting centres and special training At present it appears that less than 10 per cent of those engaged in child welfare and school medicine have held resident posts in children's hospitals Overseas pædiatricians find it hard to believe as we find it to explain that there is no special chair in London, and only one in the rest of *England, although both Edinburgh and* Glasgow have established units To find an example of how such university centres, concerned with child health and with disease in childhood, may form a liaison between practitioners, public health workers, consultants, and research workers, one must go (if one could) to Gothenburg The problems will need handling differently in the London area and in the Provinces Thus whilst provincial medical schools would naturally have a single pædiatric unit in the shape of a children's hospital in close liaison with the ancillary services of the university and the local public health authority, in London there are numerous special hospitals while each teaching hospital has its own children's unit The number of local authority areas from which patients are drawn in Greater London alone is formidable Much of the overlapping and duplication that now exist will have to be eliminated , each medical school might adopt an existing children's hospital as its teaching unit, other children's hospitals serving as centres for postgraduate teaching Of equal importance for the future of pædiatrics is a high standard of training for children's nurses , it would be lamentable if the idea prevailed that a nurse with general training who has had one or two months in a children's ward is therefore competent to become a sister in a children's ward, and it would be a retrograde step for the General Nursing Council (as has been suggested) to abolish the register of sick children's nurses

Regional planning offers scope greater perhaps in pædiatrics than in any other specialty At present few towns possess even one highly trained children's specialist, and in many areas none but the well-to-do can obtain competent pædiatric advice The wide establishment of consulting centres for practitioners, staffed by visiting pædiatricians on a regional basis, would not only raise the standard of children's practice, but also provide expert advice for welfare workers and school medical officers The strictly consultant status of the centres would not infringe the province of either the public or private practitioner Their value has already been proved in the case of orthopædics, and pædiatric centres are more than ever needed in view of the large-scale evacuation of children to rural areas The EMS provides the basis of a skeleton scheme which could be expanded rapidly Unfortunately pædiatric planning for the postwar years is overshadowed by the more immediate sequelæ of war The probable increase in tuberculous infection during childhood, the almost certain increase in juvenile delinquency consequent on evacuation and broken homes, and the possibility of a serious lowering of nutritional standards, all call for immediate consideration It is a hopeful sign that nutritional problems are being realistically faced by the provision of communal feeding in schools, and in many places schoolchildren are being taught to grow as well as to cook and serve much of their own food That the value of the midday meal at school, both to themselves and their parents, is appreciated by many children has already been shown by one enterprising county education committee[1] The memory of conditions that prevailed in Europe at the close of the last war should suffice to put pædiatric planning on the map

AZOTÆMIA AFTER ALIMENTARY BLEEDING

IT is a commonplace of present-day clinical biochemistry that a raised blood-urea can be considered as unequivocal evidence of organic kidney disease only after care has been taken to exclude various so called extrarenal causes of azotæmia The list of diseases in which extrarenal uræmia may be found is a long and growing one , it includes diabetic coma, pneumonia, gastro-enteritis, Weil's disease, acute yellow atrophy of the liver, Addison's disease and hæmatemesis In the excitement of discovering more and more diseases in which the blood-urea was high and soaring, while the kidneys in fatal cases were no more than cloudily swollen, or perhaps even fattily degenerated, the question of the actual causes of the raised blood-urea was often either tacitly set aside or decently avoided by the use of imported catch-phrases such as *azotémie par manque de sel*, or *Produktionsurämie* The published work is full of wise (but unproven) saws, and modern (but repetitive) instances The early stages when it was profitable to amass data on large numbers of patients have passed and the future seems to lie with detailed investigations on selected cases—a type of research for which the work of **McCANCE** and **WIDDOWSON**[1] on diabetic coma may serve as a model

In harvesting the biochemical lore of extrarenal azotæmia, many workers have applied themselves to hæmatemesis, perhaps because of its frequency, or because of the interest stimulated by **MEULENGRACHT'S** claims for the advantages of liberal feeding As a result, although the raised blood-urea in hæmatemesis was first described by **SANGUINETTI**[2] in 1933, sufficient material has accumulated in the past decade to justify review **BLACK**[3] has described the clinical and biochemical characteristics of this type of azotæmia The special feature which separates it from other types of azotæmia is the presence of a large amount of blood in the bowel , that this is an important source of urea has been shown by **SCHIFF** and others[4] in normal people, and by **BLACK** and **LEESE**[5] in patients with gastro duodenal hæmorrhage In addition to an increased absorption of nitrogen from the bowel there is the possibility of an increased katabolism of the tissue protein Direct evidence of this is hard to obtain, for the blood in the bowel, acting as an indefinitely large source of urea, precludes the classical evidence of tissue-protein breakdown which would be afforded by a negative nitrogen balance , but **BLACK'S** view is that there is sufficient disturbance of the internal milieu of the body by water and salt deficiency, and by circulatory impairment, to accelerate protein katabolism significantly Over-production of urea cannot be the whole story, however, for a normal person may be given much larger amounts of urea than are likely to be formed in patients with hæmatemesis without raising his blood-urea more than a very little—in other words, a normal cardiorenal system can deal with very large increases in urea production without any azotæmia developing Terminological custom has exonerated the kidneys in the phrase extrarenal uræmia , but the facts are ineluctable, and a profound fall in urea, inulin and diodone clearance shows that failure of kidney function is of critical importance in determining the rise of blood-urea **HOMER SMITH** regards inulin clearance as a measure of glomerular filtration, and diodone clearance as measuring effective renal plasma flow , if this interpretation is valid in patients with hæmatemesis, diminished circulation to the kidneys is sufficient to account for their functional inadequacy Other types of azotæmia may have a different basis , the question can only be answered by a wider application of balance experiments and modern renal-function tests

The precise ætiology of a raised blood-urea in hæmatemesis is of less interest to the clinician than its value in prognosis and treatment Most of those who have studied the subject agree with Witts[6] that the height of the rise is closely correlated with the severity of the hæmorrhage, and that a blood-urea of more than 100 mg per 100 c cm constitutes one of the indications for slow drip blood-transfusion Black outlines the considerations which govern the amount of blood to be given, a litre of citrated blood, given by slow drip, is often a suitable amount, but much larger quantities may be required in severe or repeated hæmorrhage In maintaining fluid balance there is much to support the free fluid intake which is probably the chief advantage of the Meulengracht diet, but most physicians will follow Hurst[7] in shunning its major eccentricities, such as broiled chops, timbale and tapioca pudding

Annotations

ENEMY ACTION AND MORTALITY

Prof M Greenwood, lecturing at the London School of Hygiene on July 16, contrasted the civilian mortality (necessarily among females only) which could be regarded as an excess above the normal peace time level in the first two years of the last war and the corresponding period of the present one In 1915–16 direct enemy action against civilians was not, of course, of material importance, and the number of deaths from violence differed negligibly from the 1914 figures One indirect effect of enemy action was the death of 1200 females from cerebrospinal fever—a relatively great increase from the 350 expected at the rates of 1914, absolutely, however, this was an unimportant cause of death The main excess of 1915–16 was in tuberculosis which with 24,000 deaths in each year produced an excess of about 3000 deaths or about 7% above the peace-time level He thought it not far from the truth to say that in those years the war-time tax on female life was paid in tuberculosis In the last two years things have run a comparable course, except that direct enemy action has played a much larger part The indirect effects of total war on health however (in so far as they can be measured by mortality), may have been rather less serious than those experienced by the previous generation In 1937–39 deaths of females from cerebrospinal fever were less than 300 per annum, in 1940 and 1941 they were roughly 1000 each year The disease was much more prevalent in the civilian population in 1940–41 than in 1915–16 but chemotherapy had reduced its killing power It still remains absolutely a not very important cause of death and its epidemiological history suggests no reason why it should take a major position The least reassuring feature of today is again, in Professor Greenwood's view, the debit account of tuberculosis The annual deaths from 1937 to 1941 have run 12,283, 11,052, 10,692, 11,843, 12,032 The actual toll has not been spectacular but there is clearly a testing here of our defences against an ancient and powerful enemy In the first year of the war young adults suffered most, in the second year children Again the increases at these ages can be measured in terms of a few hundred deaths, but if the war, as we are assured, must be long, those few hundreds are enough to give rise to some uneasiness Lastly we have direct enemy action, so far the largest debit item Methods hardly available in 1915–16 killed some 20,000 females in 1940–41, an addition of 4–5% to the death-rate of the prewar years Perhaps that is not very much in relation to the weight of the enemy's attack, perhaps bombing may be an expensive way of killing or frightening people That indeed may be partly the basis of Prof A V Hill's beliefs, which Professor Greenwood quoted, that "the idea of bombing a well defended enemy into submission or seriously affecting his morale, or even doing substantial damage to him is an illusion" Arithmetic must, of course, be the only accurate way of assessing the effects of bombing But one would wish to *see* the arithmetic before deciding what it demonstrates

FOOD WITHOUT WATER

In peace time, according to an estimate quoted by Sir Edward Appleton at the meeting at BMA House reported on another page, we import 3,000,000 tons of water a year in our foodstuffs Some of this waste of shipping space is already being saved by the increasing use of dried foods—most of us have lately drawn our ration of American dried eggs, for example—but when the new knowledge on drying is fully applied we may see all the food we need coming in without its water On vegetables, fruit and such the saving is enormous, but drying will reduce the bulk and weight of an average complete diet by about three quarters Apart from saving on transport, drying makes it possible to keep foods without refrigeration, so that gluts, whether seasonal or fortuitous, can be made to supply us in periods of shortage Dried milk, eggs, fruit and salted fish have for a long time been regular articles of commerce, and a large amount of vegetables were dried in the last war, though most of their antiscorbutic value was lost in the process Dried meat, too, in the form of pemmican and biltong, has long been familiar *in places where the butcher never calls* But up to the present the quality of dried meat, fish, eggs and vegetables has not been good enough for them to take the place of the fresh articles for general consumption, and little has been known about the factors influencing their palatability, keeping quality and nutritive value When this war began the Food Investigation Board of the Department of Scientific and Industrial Research, under the chairmanship of Sir Joseph Barcroft, turned its attention to these problems, among others, and they have largely been solved, thanks to the organisation of Mr Eric Barnard, Director of Food Investigation, the technical researches carried out at the Low Temperature Research Station under Dr Franklin Kidd and at Torry Research Station, and the work of Dr Leslie Harris and his colleagues at the Dunn Nutritional Laboratory to ensure the dietetic soundness of the new foods The dehydrated foods now being produced are more compact and convenient to use, particularly under service conditions, and their nutritional stability may be even greater than that of fresh foods, for the dehydrating process removes vitamin inactivating oxidases In flavour, appearance and nutritional value, when they are reconstituted and cooked, they will not be inferior to the cooked fresh foods—a triumph for scientific cooperation between the food technologists, official and commercial, and the nutritional research workers

MICROCRYSTALS OF SULPHATHIAZOLE

In the local chemotherapy of wounds and burns sulphanilamide has been the drug most used, on account of its solubility and ready availability Sulphathiazole has the advantage of activity against a wider range of bacteria, but the disadvantage of slow solution and absorption, so that if excess is applied it may subsequently interfere with wound healing as a foreign body Chambers and his colleagues[1] of Philadelphia describe the preparation of "microcrystals" of sulphathiazole by the neutralisation of a solution of the sodium salt at a low temperature, the reacting mixture being kept in violent agitation by sound vibration or some other high speed mixing device No details of this process are given A 20% suspension has the consistency of thick cream, and shows little tendency to settle out The drug was more rapidly absorbed from such a suspension introduced into rabbits intraperitoneally or intramuscularly than from a similar suspension prepared from the usual crystalline form of the drug. The microcrystals have been employed in fresh wounds, skin infections, burns and abdominal operations with gratifying results in a small series of cases both as a powder for dusting superficial wounds and as a 10% or 20% suspension, which may be injected through 26-gauge needles Chambers and his colleagues emphasise, as do Colebrook and Francis[2] for sulphanilamide, that the drug should not be dumped on the wound but dusted on the surface in a thin layer In one case, in spite of a large burned area, the blood sulphathiazole was never more than a trace This is very different from the experience of Hooker and Lam,[3] who record cases where the local application of sulphanilamide powder to burns resulted in high blood levels, in one case 33 mg per 100 c cm , with unpleasant side effects The powder and suspension were not sterilised, presumably because the application of moist heat would cause reversion to the macrocrystal, as happens with sulphanilamide powder, but no infections were attributed to its use The recent case of tetanus following the insertion into the peritoneal cavity of unsterilised sulphapyridine powder[4] has drawn attention to this possibility Microcrystals prepared by the addition of acid to the strongly alkaline sodium salt solution would not seem to be a likely source of serious infection, if reasonable precautions against contamination are taken during and after its preparation

AN ŒSTROGEN WITH A LONG ACTION BY MOUTH

IN searching for an œstrogen with a long-lasting effect when given by mouth, Robson and Schönberg[5] have examined a large number of substances including derivatives of triphenylethylene They point out that the discovery of the synthetic œstrogens placed at our disposal compounds with the great advantage of being highly active when given by mouth and that while among these stilbœstrol has been most widely used and has proved of the greatest value, it has only a short period of action so that it may have to be given at short intervals to produce a sustained effect The whole subject of the relative clinical effectiveness of œstrogens, and particularly the way in which this is influenced by the mode of administration—whether parenteral, oral, percutaneous or by implantation—has lately been reviewed by Greene[6] Robson and Schönberg have meantime obtained one new compound $\alpha\alpha$-di-(p-ethoxyphenyl)β-phenylbromoethylene (DBE) which they regard as promising, and they have compared the duration of œstrogenic action of various dosage-levels of this substance and certain other œstrogens when administered subcutaneously or by mouth The activity was determined on groups of ovariectomised mice by a method previously described for estimating the intensity of the vaginal œstrous response,[7] the measure of duration being the period until action is halved in days While DBE on subcutaneous injection was found to have a relatively high threshold further increase in dose produced a decided prolongation in its action an effect which is likened to the behaviour of the di esters of œstradiol The oral threshold of DBE proved to be similar to that of œstradiol and very much higher than that of stilbœstrol but increase of dosage resulted for DBE, in a somewhat greater increase in the duration of action Robson and Schönberg suggest that, after absorption from the alimentary canal, DBE is stored in the body and slowly released They are inquiring further into this possible explanation of its long-lasting effect and it will be interesting to know the behaviour of DBE in the type of experiment devised by Emmens[8] whereby he found that various synthetic compounds (the "pro-œstrogens" as distinct, for example, from the natural œstrogens and many compounds of the stilbœstrol series) have to be absorbed into the circulation and subsequently undergo metabolic changes to true œstrogens It remains to be seen how exceptional is the prolongation of effect shown by DBE and whether it is of special practical value in view of the powerful agents already available

TUBERCLE IN THE WORKING MAN

OUR tuberculosis service, worthy of respect in many ways breaks down in some important particulars Thus most cases with a favourable prognosis are sent to a sanatorium for 3–6 months as soon as the disease is diagnosed, and in most places treatment is given without charge to the patient, though the actual cost may amount to as much as £5 a week per bed When the patient returns to his home, however, for convalescence and rehabilitation no such generous provison is made for him , indeed, as the Socialist Medical Association point out, in a report revised since last year,[9] the scale changes from optimum to minimum If he has been incapacitated for more than 6 months his National Health Insurance benefit will have fallen to 10s 6*d* a week, and this with extra nourishment supplied in kind (and not as a right) by the local authority is all he has in place of his previous wage—unless he likes to apply for public assistance He may feel it humiliating to make such application , moreover, public assistance rates vary with the district, thus in a poor area where cases may be numerous, the funds to meet them are low, and assistance is likely to be on an inadequate scale In 1940 F R G Heaf and Lloyd Rusby calculated that a tuberculous person could only just manage on 19*s* worth of food a week if he was to be adequately fed ; Prof J R Marrack put the figure at 17*s* , but even so it was well beyond the patient's means and prices have risen since then Nor is this the only disaster the patient generally shares his home—probably a small and crowded home—with his wife and family As a rule his wife probably has to go out to work to augment the family income and the patient is thus left to take charge of the children who, lacking the protection of an ample diet, are likely candidates for infection

The association remind us of the close correlation between war industry, long hours of work and tuberculosis The present war is only driving home what we learned from the last, and tuberculosis is as usual providing a barometer of social conditions Thus the prewar steady decline in mortality has been converted into a rise in the twelve months July, 1940, to June, 1941, about 3000 more people died of tuberculosis in England and Wales and about 600 more in Scotland than in the corresponding period in 1938–39 The reasons are evident industrial life favours the development and spread of tuberculosis especially when the blackout interferes with ventilation , fatigue due to long hours of work transport-difficulties, and restrictions of diet add to the hazards It is true that unemployment is no longer an important cause of defective nutrition, but for the wage earning community as a whole, the association maintains, only about two-thirds of the increased cost of living has been met by increased income that those who have managed to increase their purchasing power have only done so by working overtime Hours in the factory in excess of 60 a week lead to absenteeism from sickness and to a fall in production, as the Industrial Health Research Board has demonstrated again and again , and among causes of

absenteeism is tuberculosis If early cases could be removed from industry while they were still easily curable and before they had infected their fellows, the death-rate from the disease could be cut down, even in wartime The association quote the findings of Dr Laszlo Banszky in a factory near London between 1936 and 1941. Routine X ray examination of 10,000 new entrants revealed active tuberculosis in 1–1 5% Among those actually employed the incidence fell rapidly after the scheme based on these findings had been in action for a few years Indeed miniature radiography offers the perfect method of detecting, among those entering industry, the early case for whom industrial work will mean danger to himself and others Unfortunately organised industrial workers are opposed to its routine use—nor is it difficult to see why a diagnosis of tuberculous disease means, for the worker, social and economic disaster If his financial position was safeguarded and his restoration to health and to suitable work systematically undertaken, the worker would welcome early treatment as much as anyone else As things are he naturally conceals his disability as long as his strength allows

The association suggest that tuberculosis should be placed in a special category under National Health Insurance and that a cash allowance should be made, sufficient to provide the relatively high standard of living the tuberculous patient and his family need They propose that notification should entitle the patient to receive full NHI benefit for a year At the end of that time his case and that of his family contacts would be reviewed by the tuberculous officer perhaps in consultation with another physician or with a local board He might already be back at work, if not, his capacity for light work would be considered by the tuberculosis officer and the Ministry of Labour representative, and further financial benefit would be granted according to his state Where domiciliary treatment has been given by a general practitioner presumably he would be included in this consultation Disabled patients might at this stage become eligible for a permanent rate of benefit either comparable with that received by tuberculous men discharged from the Forces or equal to their former wage No doubt such a scheme would need careful planning, but the need for some provision of the kind is driven home by the main argument of the pamphlet that the period of impoverishment at present inevitable between discharge from sanatorium and return to work is blocking the way of early discovery and treatment of tuberculosis in industrial workers

TISSUE EXTRACTS AND WOUND HEALING

WORKERS in Jerusalem[1] have lately demonstrated the stimulation of epithelial cell multiplication in vitro by means of heterologous adult tissue extracts, and they promise a paper shortly on the results of clinical trials of such extracts on wound healing In assessing clinical value it is to be hoped that they will bear in mind the difficulty of comparing things that are not comparable —namely, wounds different in situation and nature in different individuals and caused by different agents Experiments on animals such as those of Dann, Glucksmann and Tansley[2] would perhaps give more valuable results On theoretical grounds there is no reason to suppose that an agent which promotes cell proliferation in vitro will also promote wound healing in vivo Here again is a comparison of things that are not comparable In the case of cell multiplication in vitro a change in rate or number of cell divisions is being observed, more mitotic or amitotic divisions occur in response to the addition to the culture of one substance than to ano In the case of wound healing it was shown as long as 1898 by Loeb[3] that epithelial healing occurs by sl of cells from the edge of the wound over the bare surface the mitotic activity is in the back areas at some dist from the bare surface Thus what is being observed a rate of sliding This probably depends as much the nature of the base of the ulcer, the looseness of surrounding epithelial connexions and capacity to stretched as on distant mitotic activity Loeb's o vations have been amply confirmed in the years betw and the whole subject reviewed by Arey[4] in 1936 S then Wigglesworth[5] has demonstrated the same phe menon, with great ingenuity, in insects and has sug that the immediate stimulus for the cell division w occurs at a distance from the wound is a cell sca resulting from the slide A macroscopically v demonstration that a slide does in fact take place provided in corneal healing in those animals and in which pigment is present in the corneoscleral junc After a lesion of corneal epithelium which is exte or approaches the junction without actually touching the pigment line breaks and two pigmented limbs mo gradually down or across the injured surface of cornea As they progress from day to day the s ceases to be stainable with fluorescein, an indic familiar to ophthalmologists that healing has taken place If sections are made of the recently covered area, pigmented cells and some mucous glands derived from the conjunctiva will be found in the new covering of epithelium In a simple corneal ulcer healing is very rapid Bacterial infection and œdema from any cause delay it

TRYPTOPHANE DEFICIENCY

TRYPTOPHANE was isolated by Hopkins and Cole[7] in 1901, and soon after that it was recognised to be in all probability an essential amino-acid As such, a specific syndrome might have been anticipated from its deficiency, but this was not described for some time owing to the difficulty of providing diets which were deficient in tryptophane but perfect in all other respects. Albanese and Buschke[8] have now shown that young rats which have been nourished on a diet poor in tryptophane develop cataracts, vascularisation of the cornea, alopecia, defects in the enamel of the incisor teeth, and (if male) atrophy of the testis and aspermiogenesis. Adult animals do not develop the cataracts or the defects in the incisor teeth It is apparent that continuously growing epithelial structures bear the brunt of this deficiency, but in the opinion of these two observers the lesions are not confined to those tissues, for there is also a retardation of growth and a loss of skin turgor The similarity of the ocular changes to those produced by a riboflavin deficiency is interesting An editori article in the same number of *Science* suggests that sin cereal proteins contain considerably less tryptopha than animal proteins it is dangerous to rely solely o cereals as the source of amino acids in human diets—might be done in a postwar world faced with grave shortages of other kinds of food This may be so, bu humans have a much lower rate of metabolism than rat and even the most unbalanced human diet is likel to contain sources of protein other than the cereal The importance of Albanese and Buschke's findings i human nutrition has yet to be proved If and when it i there will be one more reason for seeing that everyon rich and poor, native and European—gets a sufficienc of animal protein

In England Now

A Running Commentary by Peripatetic Correspondents

WE seem to have settled down at last to a stoical acceptance of the hardships of war—sewing-cotton for ligatures no eggs and bacon for breakfast no liquid paraffin, and the ache of long-disused bicycling muscles One overfull day follows another and the spices of life seem somehow forgotten This year, last year, they seem so much alike Yet every memory of the summer of 1940 seems to be cut crystal clear in my memory As we stood on the brink of destruction during those lovely summer days every flavour that life could offer seemed infinitely sweet, for there seemed to be so sharp an edge to living Savour each morsel to the full roll it around the tongue and store it away in the memory for it may be the last Each moment seemed so much a lingering farewell to all one had loved that I swear the roses of those golden days were sweeter, the dew softer, and never did jasmine drench the moonlight as it did that night when the distance glowed red under our first air-raid It is two years ago and yet I can recall every moment of a stolen bathe Was it to be the very last ? The barricades were going up on the beaches and the wagons were being dragged across the lanes, but the water was still silver cool and it was heaven to float half asleep on the still sea and ecstasy to lie on the hot sand And all the way home the hay was sweet in the fields I was back in my youth again with blood running fast There were adventures too in those days Coming home one night from a distant cottage hospital, just as the pubs closed and the LDV came on duty, I was stopped ten times in as many miles by a swinging red lantern Each time, with a loaded double-barrelled shotgun thrust in my ribs, I had to fumble for my identity card Merciful providence alone brought me safe home that night But my most treasured memory is of a night in September of that year I was spending a week-end on Exmoor and my room overlooked the village green I woke to the sound of the church bell ringing Then the night was quiet again with the quiet of the countryside asleep Presently a steady clip-clop was heard, and into the moonlight rode the squire, an old soldier, thin and very straight on his hunter He had his revolver with him, and he was followed by two grooms, each with a shotgun In the rear came a handful of farm lads on Exmoor ponies and they had their bill-hooks slung from their waists Through the faint white mist of the summer's night they rode away up on to the moor Clip clop, clip-clop All was well Saint George had gone forth to do battle with the Dragon

* * *

A peripatetic correspondent recently wrote of the illiteracy of the medical student south of the Tweed I entirely concur and extend what he wrote to other students Mine are southrons and almost completely illiterate and I maintain that this illiteracy has developed since 1918 What have the public and secondary schools been up to all this time ? The annoying thing is that I have to pass the large majority because, under the smoke-screen of words they raise against my scouting I think I discern a knowledge of 40% of the facts of physiology It is a grief to me that such people should be let loose on an unsuspecting public as people of education They often write sheer nonsense which a moment's thought would have shown to be such The vagus—a nerve they well know to be mainly visceromotor innervates (spelt " enervates ") the external intercostals, the diaphragm (" diaghram ") and the muscles of the abdominal wall The phrenic rarely, in their answers, enervates the diaghram, but shares the other imaginary functions of the vagus This, of course, is Johnsonian " sheer ignorance, madam " but they ought not to be so ignorant so often The sentences they write, though they pause and analyse, often add nothing to knowledge What do you make of this ? " Differences of pressures in the chambers of the heart are measured by connecting needles to smoked drums " Or of this ? " The heart is attached to a fine quartz fibre suspended between two poles " Darts ? Or the Rugby football goal ? I guess, but there was no confirmatory evidence, that Piper's manometer and Einthoven's galvanometer respectively were intended I have only a hunch that this was so And the jargon they write ! What exquisite examples they would have afforded to Quiller-Couch and A P Herbert " Hæmoglobin takes up oxygen in large proportions " " The bundle of His is adapted to conduction " " This compound is very important in the function of the red blood corpuscles " " the Purkinje fibres which ramify the majority of the ventricles." (What an odd mathematical problem to find a majority among two items) Two adjacent students—I do not hint for a moment at collusion—wrote " This is of great importance with regard to the function of the cell in connection with respiration " and " This becomes important in relation to the carriage of carbon dioxide by the blood " Two minds with but a single woolliness between them ! Jargon slop woolliness and make-belief in education ! And yet with this pulp of a mentality they go out into the world, and make good That's the startling thing But this proves nothing Least of all that education is no good

Are all undergraduates so illiterate or is it only those who read science who so lack " nous," precision and power of expression ? Anyhow our schools and universities will have much to answer for at Doomsday

* * *

Cedric has just come back from camping with some other little thugs at Brightsea He has improved enormously in every way, a change which his mother vaguely attributes to those thick woollen combinations and Auntie to the ozone which as the LNER points out is unusually dense down there A Recording Angel, however, has other views In general his severance from home life and the alterative of new surroundings and diet have been beneficial In particular, going down in the train he was set on by his friends and got a large bruise of the thigh Clever people call this autohæmotherapy , it acts in the same way as trying out one's repartee at home first or sparring with a younger brother before taking on the boy down the street He was far too busy for the first three days to open his bowels This gave him a sour mouth, to which green apples were irresistible His pylorus said, " Hoots, if you'd only give me food like this for two months, my lad, I'd make you a stomach an ostrich might be proud of ! " It kept on saying it all night and the lower tubes joined in the chorus During this hymn of praise all the proud racial groups in the large intestine, who for the last ten thousand generations had never had to face anything worse than a mild cataclysm from syrup of figs, were swept away A sturdier lot, who managed to run the acid blockade, took their place , they came from sewage-contaminated ditch-water which he drank on a very hot day, some uncooked food stolen from the store-tent and much favoured by the latrine flies and a host of grasses, well-manured straws and bits of wood which he sucked or with which he picked his teeth Nor was this all—in a fight with a friend Cedric bit his hand and swallowed some oxyuris eggs His eosinophils were delighted, they hadn't had such an outing since two years ago when he hogged some bad fish which had been thoughtfully put aside for the cat Outside the narrow world of the gut other happy events were taking place His leucocytes were having splendid sport they were partially mobilised all the time and dealt with sunburn torn knees, hundreds of mosquito gnat and horsefly bites, and of dog, boy and wasp bites one each The neglected aliens disposal board so important to his forefathers also worked day and night , nettle stings, cockles, berries, a legion of moulds and pollens and the excretions and emanations from his little friends were among its chief clients Nor must we forget his fibroblasts, who owing to many surface abrasions were able permanently to retire their older members, thus making room for new blood Many muscles were fully used for the first time—e g , the abductor hallucis—or put to a new use like the masseters in defæcation Mentally he became much more alert This was partly due to the great depth of his sleep, the result of his getting plenty of CO_2 under his blankets and those excellent hypnotics, the effluvia from the axillary and inguinal region, and partly to his realising that he was now in an unprotected state, and that pain hunger and/or indignity followed any failure of defence precautions Psychically also he improved In " helping " a farmer thresh he killed and maimed a number of rats, thus proving his superiority over another mammal and this sadistic orgy had a most tonic effect on his ego (nee id) Spiritually—if one can use this word with such as Cedric—perhaps he was born, for in that for the first time he saw the dawn (from the latrine during the apple deluge), in that he felt the immensity of the sea (and swallowed several pints of it), and in that he smelt the mists from lowland leas at dusk, which he compared unfavourably with those from a friedfish shop, it may be hoped that he glimpsed the face of his Creator

* * *

I had a partner once who vowed that he would write, before he died, a book with the title "Anatomy and Toxicology for Would-be Suicides and Murderers" The determination came at the end of a long operation we had done together on a girl with a severe self-inflicted abdominal wound Actually she was more unlucky than ignorant, for in talking with her doctor an hour or two before she had made some remark and added "With my hand on my heart, I swear it is true," and she put her hand on her left breast as she said it The doctor, who never dreamt of the outcome of his joke, teased her with, "Don't be silly, your heart isn't there it's here," folding his hands on his prominent paunch Then only a few days ago I saw a woman who had wandered into her bathroom in search of a draught to end all trouble She first came on a bottle of carron oil and hopefully swallowed the lot Finding that she felt if anything a little better for this drink she went to look for something more potent and this time put away the best part of a bottle of lysol So well protected with oil were her mouth, œsophagus and stomach that she came to little harm apart from having to submit to the indignity of the *stomach pump* When I told this to my late partner he said that he now planned an appendix of anatomy for abortionists, having recently removed a vast and jagged piece of slippery-elm bark from the bladder of a woman who had thrust it hopefully into the wrong orifice

* * *

I have had enough experience of parents' matches at preparatory schools to know that they seldom, if ever, go according to plan The theory is, of course, that the parents, by the exercise of their superior skill and cunning, so contrive matters that the boys win, by one run or thereabouts, in the last over of the day You can take it from me that it never works If the parents bat first they are all fiddled out for an absurdly small total and lose by 10 wickets If they field first they start by tempering the wind to the shorn lamb—bowling long hops to leg and artistically dropping simple catches—only to find that the opening pair of little brutes, having thoroughly played themselves in, can't be separated, with the result that the boys declare with 250 for 3 on the board and the parents as usual rabbit out for about 50 The prospect of playing for the parents at a large school for large girls was even more alarming I have now reached an age when I no longer look forward to standing up to swift bowling from a lot of beefy girls—and how beefy they are these days, to be sure! However, there was no wriggling out of it and as the father of a small and new big girl I felt that much depended on me The parents batted first and when I went in—even more nervous than usual in such circumstances—we had lost 5 wickets for a matter of 20 runs As if they hadn't enough to cope with male parents were issued with pieces of wood, sawn off, narrow and unspliced at that, to serve as bats By watching the ball with extreme care I survived a shaky over or two and began to get the measure of things I was ably partnered by an absurdly young-looking father We took the score to 80 and were *still* together at the tea interval when, to my relief, we were forcibly retired Thanks to some brisk hitting by a couple of athletic mothers the parents' total topped the hundred and when stumps were drawn we had got half the young ladies out for 60 so it was a pretty even game I was told afterwards by my small daughter that my performance had given satisfaction and that I had even been described as a classy bat, that ought to do her a bit of good Appropriately enough I bowled a couple of maidens

For Positive Health we always preach
And Positive Health we sometimes teach,
But Positive Health we never reach,
It's cranky and slightly boring

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS M P

THE last days of the session before the recess have been crowded with business and with meetings in committee rooms at which distinguished people have come *to give Parliament information on matters of grave* public concern M Maisky, the Soviet ambassador, addressed members on the military situation in Russia a Frenchman, lately escaped from Lyons, spoke with great eloquence and persuasive conviction on the present situation in France, and Mr Nash, New Zealand Minister at Washington, described the situation in the Pacific No member has any excuse for not realising that we are in truth in the midst of a world war And the adieux some of us have made to Sir Arthur Salter, parliamentary secretary to the Ministry of War Transport, on his return to his office in Washington, have underlined this world-war aspect The air linked framework of the post-war world is already beginning to appear in the air-linked civilian and military staffs of the United Nations who move from continent to continent as quickly as four years ago we moved from London to Paris All problems, and not least all medical problems, must be looked at in the light of this revolution in transport and communications and, complementarily, in the pooling of our personnel under lease lend arrangements

The colonies are now part of our back-garden and when Dr H B Morgan in a Colonial Office debate criticises administration there—"neglected food-supplies, extensive diseases, poor medical services, destitution, poor wages, people divorced from the land, high illegitimacy rates, juvenile delinquency, minimum welfare, poor educational standards and facilities"—he is criticising things which will affect us tomorrow as closely as the slums of London and Glasgow affected us yesterday It is indeed significant that we have had two Colonial debates in such quick succession The disasters of Malaya and Singapore and Burma have made us colony-conscious Dr Morgan advocated, among other things, a federated medical service for the West Indies open to both European and West Indies on equal terms There is no more urgently needed reform in all the Colonies No real progress can be made until health conditions there approximate to those in Western Europe

Mr H Macmillan, Under-Secretary of State for the Colonies, said in his reply that in terms of services—medical services and so on—standards have risen in the colonies during the war But in the West Indies the submarine menace in the Caribbean is preventing this and in Rhodesia and Nigeria there is the complication of the introduction of forced labour especially for tin mining What the effect of this on health conditions will be is not easy to forecast But unless the arrangements for huts, sanitation, water and food are a great improvement on the conditions at prewar mines the results may be deplorable But the Colonial Secretary had said that he did not like forced labour and would get away from it as soon as possible What the conditions become will depend on the duration of the war

* * *

Other business has been the passing of the United States of America (Visiting Forces) Bill which takes American soldiers out of the jurisdiction of British courts *to their own court-martials and which may provide* some difficult situations with regard to medical evidence We have also had a debate on conditions in Ordnance Factories and a vindication of their efficiency by Sir Andrew Duncan

* * *

On the last day of the session Mr I C Hannah arose on the Conservative benches, duly called by the Speaker, and at the top of his voice cried aloud "Who can count the dust of Jacob," which somehow reduced the whole house, a crowded house, to helpless laughter, front benches and back benches going down like rows of cards *This was the introduction* to an historical disquisition on the contacts of Judæa and Mahomet, on ancient history and modern, and incidentally, on the possibility of recruiting a Jewish and Arab Army in Palestine It was a great oratorical feat for it kept the attention of the house—a delightedly laughing attention—and there are not too many amusing speeches in the House these days And so, after a statement on prisoners of war by Sir J Grigg and a discussion on the transfer of women munition-workers from one part of the country to another, away to a recess which members think too long because they fear it may be curtailed by a grave crisis in the war

QUESTION TIME

Pensions for Cripples

Mr B V Kirby asked the Paymaster General whether, in aming the Government's post-war reconstruction programme, would consider the desirability of introducing state ensions for all persons permanently crippled, thus relieving em of the pain and anxiety of competing in the labour arket with those more physically fitted for the life of industry id commerce —Sir William Jowitt replied This matter lls within the scope of the committee on social insurance id allied services presided over by Sir William Beveridge understand that the committee have received evidence from rganisations and persons concerned with the welfare of ripples and that the question is likely to be dealt with in the eport

Tuberculosis in Wales

Mr James Griffiths asked the Minister of Health what teps had been taken to deal with the waiting list of patients or admission to tuberculosis hospitals and sanatoria in Wales -Mr E Brown replied I have under immediate considera ion the possibility of releasing from the Emergency Hospital cheme a further 200 beds for tuberculosis cases in Wales

Pension Cases Referred to Specialists

Mr James Barr asked the Minister of Pensions how many ension cases had been submitted to the panel of independent nedical specialists since the declaration of war, and with hat result —Sir W Womersley replied 127 cases have een so referred, of which 46 were recommended for admission o pension

Admission of Women to London Medical Schools

Prof A V Hill asked the Minister of Labour whether he was aware that most medical schools in London refused to accept women medical students, although many with good educational qualifications were anxious to enter, and whether, in view of the fact that students beginning now would not be medically qualified for several years, he would refuse to reserve any more men to commence the study of medicine in these schools unless they agreed to take a reasonable proportion of suitable women —Mr Ernest Bevin replied I am aware that some medical schools in London do not accept women students Whether such schools should accept them is a question for consideration by the committee on medical schools I must, however, take all relevant facts into consideration before I agree to reservation

Reservation of Dental Students

Prof Hill asked the Minister whether he was aware that a number of foreign refugee dentists were at present unemployed, and whether, in view of the shortage of man power, he would cease to reserve further dental students from military service until these refugee dentists were absorbed, either in practice with temporary registration, or as students to obtain British qualifications —Mr Bevin referred to the reply given by the Minister of Health on July 14, and added that the suggested reduction in the quota of British dental students would not be practicable since quotas of dental students are fixed with a view to maintaining the future supply of British dentists, and it would not be proper to reduce them to make room for students who may not in the ordinary course be practising in this country after the war

Shortage of Midwives

Mr G C Hutchinson asked the Minister of Health whether he was aware that it is the policy of the Central Midwives Board to require pupil midwives during the second period of their training to reside in the homes of district teacher midwives and to permit a limited number of pupils only to reside during this part of their training in an institution, that, as a result, only four pupil midwives could now be trained in the maternity service maintained by the Ilford borough council, and whether, in view of the need for training a sufficient number of midwives and the difficulty of arranging for pupils to reside with district teachers, especially under war time conditions, he would take steps to secure some modification of the present policy —Mr Brown replied I am aware that the policy of the CMB is to require pupil midwives to live with their district teacher during a part of their second period of training, so that they may receive the full value of the domiciliary training The shortage of practising midwives is not due to a shortage of pupils, but to the failure of many qualified midwives to practise I do not, therefore, think it is necessary to ask the board to modify their policy

Mr Hutchinson Is the Minister aware that the Ilford borough council would be able to train a very much greater number of pupil midwives if they were permitted to reside in the institution instead of with the district teachers ?—No further reply was given —Professor Hill Does the Minister consider it a good thing to allow young men to stay out of the Services merely to prevent women entering the medical profession ?—Mr Bevin I do not deal with reservations on that basis No one regrets more than I do the rigidity of the medical trade union rules

Diabetes as Cause of Death

Replying to a question Mr E Brown said Before 1940 the statistical classification of deaths in respect of certificates attributing the cause to diabetes in conjunction with one or more other diseases was decided by means of rules giving the precedence of one disease over another as laid down in the Registrar General's manuals of the International List These rules gave a high precedence to diabetes over other diseases From 1940 classification has been carried out in accordance with the order of statement of the various causes on the certificate by the certifying medical practitioner, with certain exceptions laid down in the manual issued in 1940. Since diabetes is frequently certified as merely a contributory cause of death, in association with another disease considered by the certifier as more important, the effect has been to reduce the number of deaths classified to diabetes in the statistics of cause of death, and the corrective factor to be applied to numbers of deaths in years prior to 1940 is 0 69 In the recent quarterly returns of the Registrar-General the necessary correction has been applied to the diabetes deaths there shown for years 1938 and 1939

Infectious Disease in England and Wales

WEEK ENDED AUG 1

Notifications —The following cases of infectious disease were notified during the week smallpox, 0*, scarlet fever, 1456, whooping-cough, 1116, diphtheria, 650, paratyphoid, 6, typhoid, 9, measles (excluding rubella), 6476, pneumonia (primary or influenzal), 418, puerperal pyrexia, 160, cerebrospinal fever, 69, poliomyelitis, 9, polio-encephalitis, 4, encephalitis lethargica, 1, dysentery, 64, ophthalmia neonatorum, 81 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on July 29 was 1561, including scarlet fever, 2[illegible], diphtheria, 146 measles, 375 whooping-cough, 238 enteritis 65 chicken pox 87, erysipelas 38, mumps, 60 poliomyelitis 2 dysentery, 35, cerebrospinal fever, 14 puerperal sepsis, 18, enteric fever, 4 german measles 2 other diseases (non infectious), 118, not yet diagnosed 104

Deaths —In 126 great towns there were no deaths from scarlet fever or enteric fever, 3 (1) from measles, 4 (2) from whooping-cough, 12 (0) from diphtheria, 42 (11) from diarrhœa and enteritis under two years, and 6 (0) from influenza The figures in parentheses are those for London itself

Birmingham reported 5 deaths from diarrhœa, Ipswich 4

The number of stillbirths notified during the week was 234 (corresponding to a rate of 35 per thousand total births), including 34 in London

---

* In the week ended July 25 2 cases of smallpox were notified, 1 in Westminster and 1 at Stone Staffordshire

---

Medical Sickness, Annuity and Life Assurance Society —At the annual meeting of this society, held on July 27, Mr R J McNeil Love, chairman of the board of directors, who presided, said the amount of new life assurance business was only slightly smaller, but the claims by death had been lighter and the surrenders fewer On the sickness fund the claims had been considerably lighter and the premiums were up a little The funds of the society had been increased by £173,537, and now stood at £2,355,319 The quinquennial valuation at the end of last year had disclosed a surplus of nearly £83,000 on the life assurance and annuity fund and of £120,850 on the sickness fund

SCOTLAND

PREVENTIVE MEDICINE ON CLYDESIDE

SOME months ago an important experiment in preventive medicine was begun in the Clyde basin, where nearly half the insured population of Scotland is huddled, and where sickness-rates before the war were high General practitioners in this area were asked to refer to the EMS regional officer young people of 15–25 among their patients who were engaged on war work and seemed likely to benefit from further investigation or treatment In his Honyman Gillespie lecture in Edinburgh on July 30, Dr Andrew Davidson, chief medical officer for the Department of Health, described how the scheme had worked in practice Just under 700 patients have been dealt with and about half of these have been admitted to EMS hospitals or convalescent homes Most of them were young debilitated workers, complaining of fatigue, vague aches and loss of appetite, in whom little gross organic disease was found, but some had anæmia, bad teeth or unhealthy tonsils to account for their symptoms, others were convalescing from influenza, pleurisy or pneumonia, and a few were contacts in whom the tuberculosis officer had found no signs of disease The next biggest group of patients included those suffering from anxiety states and those with repeated attacks of minor respiratory illnesses whose convalescence had been prolonged. Most of these patients had a history of long hours of work, uncongenial work, changing shifts, excessive travelling, unsatisfactory diet—this in spite of local canteens—too much smoking and so forth On the whole late hours and ill-spent leisure were not common Many only needed a rest, change of scene and good food to restore them and they were sent directly to convalescent hospitals But when the ordinary overhaul left any doubt about the possibility of more serious disease they were first sent to hospital for a thorough examination Reports from discharged patients leave no doubt of the good the scheme has done, but the after-care of these young patients is equally important and it is hoped as the experiment develops, with the help of the Ministry of Labour, to arrange from time to time to review the work of these people in relation to their physical condition

EDINBURGH SCHOOL HEALTH SERVICES

Last month the Edinburgh education committee approved a reorganisation of their medical and dental services which cannot, however, be put into operation until after the war The new service will cost £32,000, or nearly double as much as the old one Special stress is to be laid on the care of the children's teeth, and there will be ten dental officers instead of seven The scheme will also include part-time oculists and aurists

GEORGE KEPPIE PATERSON

Dr G Keppie Paterson, who died last month at the age of 81, was elected to the fellowship of the Royal College of Physicians of Edinburgh in 1895 and was one of its senior fellows After graduating with honours from the University of Edinburgh in 1882 he was for over ten years assistant to Sir Alexander, then Professor, Simpson Dr Paterson was an enthusiastic worker for the Edinburgh Medical Missionary Society and for more than half a century was associated with the Livingstone Dispensary in the Cowgate, of which he was convenor and consulting obstetrician Travelling and music were his hobbies and for many years in the midst of a busy general practice he found time to run a choir at the dispensary

WELFARE OF SCOTTISH MINERS

The Secretary of State for Scotland has appointed a committee under the chairmanship of Sir David King Murray to report what measures should be taken to enable the fullest use to be made of existing and potential resources in the Scottish coalfields and what provision of houses and other services will be required for the welfare of the mining community Eight of the committee's twelve members are representatives of owners and workers The other four are the county clerk of Stirling, Mr F C Mears, FRIBA, planning consultant for East Lothian, Midlothian, Fife and Greenock, Mr Thomas Brown, consulting mining engineer of Glasgow, and Mr A S McKinlay, MP, deputy chairman of Glasgow corporation It is to be regretted that there is no medical member

MEDICINE AND THE LAW

Advertised Cures for Diabetes

FURTHER prosecutions during July gave fresh publicity to the fact that, under section 8 of the Pharmacy and Medicine Act, 1941, it is now an offence to advertise any article in terms calculated to lead to the use of the article for the purpose of treating diabetes, tuberculosis, epilepsy and other specified diseases

In a case at Bristol, where a defendant was fined £5 on the prosecution of the Pharmaceutical Society, it was said that he had formerly advertised in a magazine called the *Herb Doctor* a patent medicine called 'Daddy's Deodorised Viscous Oil' for treating diabetes This advertisement had appeared long before the act was passed Recently one of the society's inspectors had written to ask the defendant for particulars of this cure In his reply the defendant said that he was no longer permitted to describe the medicine as a remedy for diabetes He seems, however, to have enclosed a printed circular stating that it was a cure for diabetes Section 8 (2) of the act declares it to be a good defence to prove that the advertisement was published only so far as was reasonably necessary to bring it to the notice of persons of certain named classes, including members of Parliament, hospital committees, registered medical practitioners, registered nurses and registered pharmacists Section 10 (2) says it shall be a good defence to prove that the advertisement was published only in a publication of a technical character intended for circulation mainly among persons of certain named classes, including registered medical practitioners, registered nurses and registered pharmacists Section 15 places on the Pharmaceutical Society a statutory duty to enforce section 8 and to employ its inspectors for that purpose The Bristol defendant's legal representative took the ingenious point that, as the prosecuting inspector was a registered pharmacist, there was a good defence When this contention failed, he complained that his client had been trapped by the society in a not very worthy manner

In another case, heard at Dolgelley, a Caernarvon company, T S Ingham, Ltd, was summoned for advertising a product by means of a booklet entitled "The Conquest of Diabetes" Here the prosecution seems to have been undertaken under the act by the local food and drugs authority A Merioneth weights and measures inspector said that his assistant bought a bus ticket on which was an invitation to write for a free copy of this booklet He did so, and after sending money received a bottle of tablets The booklet described the discovery of a herb in South Africa and its cultivation and preparation as an effective treatment for diabetes The weights and measures inspector disclaimed making any accusation against the merits of the tablets—a fact which the defendant's solicitor emphasised "You don't mean to say," asked Dr John Jones, the presiding magistrate, "that this is a remedy for diabetes, do you?" "I am instructed that it is," replied the solicitor, "if you read this booklet, I think you will find it is an adequate remedy for diabetes" The solicitor explained that the advertisement on the bus tickets was arranged for in 1938 but evidently the old stocks were not yet exhausted The Caernarvon company had asked the omnibus company to discontinue the use of these tickets, but the Government restrictions on paper made this impossible The booklets were kept in stock for the foreign and colonial trade where, said the solicitor, their use was legal The defendant company was short of staff, owing to the war, and Mr T H Ingham, one of the two directors and also the secretary of the Caernarvon company, was unable to give his full attention to details as he was a sergeant in the Caernarvon special constabulary The magistrates imposed a fine of £5, including costs

It may be added that the act requires the consent of the Attorney General to be obtained before proceedings are instituted under section 8 This requirement presumably ensures that frivolous and unnecessary prosecutions are not undertaken

Letters to the Editor

DIPHTHERIA IN INOCULATED PERSONS

SIR,—The paper by Dr Glover and Professor Wright your issue of Aug 1 brings again into prominence the uestion of the value of the subsequent Schick test ter immunisation against diphtheria Bousfield and hers have shown that the subsequent Schick test incates a percentage of failures in immunisation which ries with the type of prophylactic used and the chnique and dosage adopted, and it appears that failure-rate of 0 5% is not uncommon even with the est material and technique The case-incidence in oculated persons represented by the figures of Glover nd Wright is approximately 0 72%, a figure sufficiently ear to the foregoing, allowing for the variation in aterial used, to be accounted for by a normal failure-ate The case-fatality rate is low enough to suggest at even in the apparent failures the immunisation ay have had some modifying effect on the course of he disease and the claim that from the point of view f herd immunity the results are satisfactory is quite ustifiable So long, however, as immunisation is urely voluntary the necessity for popular education in ts value is of paramount importance The scientist will be more than satisfied with figures such as these, but those who are concerned with anti-immunisation propaganda will be able to focus public attention on the fact that 396 cases, with 11 deaths, occurred in immunised ndividuals during the period under review and to say o the parent “ one of these children might have been yours ! ”, a propaganda point with direct human appeal Even to be honest with the parents who bring their children to the immunisation clinics and to say that one child in every two hundred will not obtain protection is a dangerous weakness in our case for general immunisation, since the parent is naturally more concerned with the safety of his own child than with the more academic point of the freedom of the community from epidemics

The low incidence of the disease among children found to be subsequently Schick-negative and the infinitesimal proportion of fatal or serious cases among Schick-negatives does, however, put us in a position to say to the parent of the subsequently tested case that we can very nearly guarantee immunity from serious risk, or, if the test is positive, that immunisation having failed the danger of diphtheria should be carefully borne in mind if any symptoms develop By carrying out the test we can eliminate the case of the parent who, lulled into a false sense of security by the knowledge that immunisation has been carried out, allows the disease to progress to a dangerous stage before calling in the doctor

In the large city the technical work of Schick-testing is formidable, but should not be insuperably difficult In the small town, where a single serious case in an immunised child may completely wreck an immunisation scheme by the spreading of plain or more frequently embroidered rumours, the task is easier and much more essential In this town, for instance, although not a single case of diphtheria has yet been recorded in an immunised child, a fatal case in a neighbouring district, in a child inoculated but not subsequently tested, caused a considerable falling off in the numbers applying for immunisation The Schick-testing of sample batches, a useful method of discovering the efficiency of a scheme as a whole, does not help to solve the problem of the individual

One wonders, too whether the complete abandonment of the preliminary Schick test is wise If the incidence of the primary negatives is over 30%, the saving of time and materials resulting from a preliminary Schick is great enough to be worth the trouble, and such a high incidence of immunity is possible in certain circumstances In this town the after-effects of a considerable epidemic of a low-grade clinical type in the winter of 1937–38 were producing, in 1940, a preliminary Schick-negative rate of this order With the passage of time and the growing up of infants who were too young to be exposed in that epidemic, it is now found that this high negative rate only applies to children over 10 years, so that the preliminary test is used now only in the older groups, but the practice of carrying out preliminary tests on sample batches in order to obtain some index of the proportion of naturally immune children might prove worth while as a general policy in urban areas

Accrington JOHN D KERSHAW

INCIDENCE OF RHEUMATIC FEVER

SIR,—Morris and Titmuss in their valuable article of July 18 showed the power of the social factor over the mortality from rheumatic heart disease, but I think that their findings cannot simply be applied to the problem of incidence of the disease It is one thing to show that once a patient has developed rheumatic heart disease the mortality rises steeply with poverty, but quite a different matter (pace your editorial) to show that in acquiring acute rheumatism poverty is peculiarly potent Indeed the only figures for economic status that Morris and Titmuss could quote showed that deaths from rheumatic fever at 20 years and upwards are not related to poverty These figures they dismissed on the ground that “ rheumatic fever is important only in childhood ” , and surely this statement of theirs is an exaggeration Being interested in the problem, I have made routine inquiry into the family history of my patients for rheumatic fever, rheumatic heart disease and rheumatic chorea (which I shall call the rheumatic diseases for brevity)

(a) In 300 “ control ” patients treated for miscellaneous medical diseases, one or more cases of the rheumatic diseases occurred in 41 of their 300 families Thus, in this district (Deptford and Greenwich) among 100 families I can expect some 14 familes to have a case of the rheumatic diseases in a member other than the one questioned

(b) In 150 patients who had suffered or were suffering from the rheumatic diseases I took family histories At least one additional case of the rheumatic diseases occurred in 48 families—i e , an incidence of additional cases in 32 families per 100 “ rheumatic ” families

What is the explanation for this excess over the controls ? Possible explanations are poverty, infection or contagion, and/or familial predisposition ! The 150 rheumatic families came from the same district and the same social groups as the 300 others Yet once a case of the rheumatic diseases had occurred in a family, the incidence of *further* cases in those families was greater than the incidence of *first* cases among the controls Infection or contagion is an unlikely explanation—it is common for acute rheumatism to arise in different members of a family at intervals of many years I conclude that a familial predisposition is likely, but, once rheumatic heart disease is acquired, poverty is specially important in determining mortality Emphasis on the sensitivity of the disease to social inequality may be overdue, but stress on hereditary influence is not therefore premature

I thank Dr W Allen Daley, medical officer of health of the London County Council, and Dr B A Young, medical superintendent, for permission to publish this letter, but I am solely responsible for the views expressed

Greenwich ELI DAVIS

SUCTION DRAINAGE OF TUBERCULOUS CAVITIES

SIR,—In your annotation of Aug 1 (p 130) you say, “ The operation improves the general condition of the patient by reducing toxæmia and reducing cough and sputum ” As one who has been associated with a comparatively large number of cases treated in this way, and whose function it has been to select suitable cases and observe their subsequent progress, I have formed the opinion that in a certain proportion of cases the immediate improvement in the well-being of the patient has been quite out of keeping with the mechanical results achieved Neither has the patient’s improved general condition been essentially due in all cases to the abatement of pre-existing symptoms such as cough and sputum I agree that where these symptoms have been prominent beforehand the patient experiences considerable relief from their modification after cavity drainage, and this relief often justifies the continuance of drainage where there is a wide-open bronchus and the cavity shows no signs of closing But the almost immediate general improvement has often been even more striking in persons who have not previously complained of cough and from whom sputum was unobtainable by ordinary methods Two somewhat anomalous cases may illustrate my point In the first the cavity was "missed" at the operation, no drainage took place, and the catheter was removed after two days The patient appeared, however, to be better for the procedure and the large cavity rapidly diminished in size and may by now have closed completely In the second case there were at least two large cavities in each lung Drainage of one cavity was successfully undertaken and it is no longer seen on X ray In spite of the presence of three equally large untreated cavities elsewhere, the patient, who is a good witness, is emphatic as to the immediate improvement in his well-being which followed the operation I am not prepared to attach any significance to the fact that now, some two months later, the cavities in the contralateral lung are much smaller, for they were obviously distention cavities, which may well fluctuate in size

The apparent detoxication of a certain proportion of patients which has been noted is difficult to correlate with the bacterial changes which take place within the cavity, for, whereas the preliminary specimens are almost invariably sterile, within a few days both the cavity effluent and the catheter track become heavily infected with secondary organisms I have not felt satisfied that mechanical considerations provide a complete explanation of the frequent clinical improvement Can it be that the claims of Lavalle (*Lancet*, 1937, ii, 1299) to influence favourably the course of tuberculous disease both in bone and in lung by driving an instrument through healthy tissue down to diseased tissue are worthy of serious consideration ? He claims that by the process of lung puncture in about 200 cases he has produced in 76–80% decreased sputum and physical signs, and X-ray changes which show "absorption of the lesion and increased fibrosis" The method is, on the face of it, crude, empirical and apparently devoid of scientific basis, and as such it makes no appeal and has received little or no attention from phthisiologists in this country, although I have seen a series of orthopædic cases treated with apparent success If results are indeed achieved by this strange technique, I should be inclined to attribute them to a form of gross shock therapy It is not inconceivable that tissue response might be modified, temporarily at least, by local trauma In the Monaldi technique we are submitting the patient to the same operative procedure, though our attention is directed to a different focus Is it possible that in some of our cases we are observing the same clinical phenomena which have led Lavalle to make his therapeutic claims ?

Harefield, Middlesex L E HOUGHTON

THE STUDY OF ÆTIOLOGY

SIR,—To Professor Ryle's list mentioned in his article of July 11 (which may be required, and for whose assistance workers in the field of ætiology will be grateful), might I make two all-important additions—system and statistics These are of immediate and practical importance In a year's analysis of my weekly list of panel patients I found that only an average of 3 6% were inmates of hospitals If any attempt is made to correlate this 3 6% with the rest of complaining man it is obvious that the aid of statistics must be sought By that science it is not only possible to test one's own hypotheses, it is easy and interesting to test the ætiological assumptions of workers whose opportunities are limited to the hospital type of patient

The study of ætiology as it is peculiar to general practice seems to fall into three spheres (*a*) the relationship of minor maladies to major diseases, (*b*) the relationship of a malady to the state of nourishment of the body at the time of its occurrence, (*c*) the relationship of the cause of death to the state of nourishment of the body throughout adult life It is, therefore, the study of a lifetime and while statistics are used to analyse and correlate the various studies it would appear that explanations must be sought in physics as well as physiology, for no study of cause can be complete which does not seek to reach out towards the common science of cause With the inevitably increasing delegation of the diagnosis and treatment of disease to the clinical units of hospitals and nursing-homes, the general practitioner should be finding more time to devote to this branch of his work, and with that conception of his duty may I allowed to comment very briefly on the BMA Pl Commission's interim report

In the twenty-five years which I have spent on corded study I have accumulated records which oc 47 sq ft of wall space Research workers know the best work can be done when one can be reaso assured of several hours of uninterrupted study Gene practitioners can only find those late at night I nev know the evenings when I may wish to look at some of the records, nor to which section of the records the study lead me If, through the adoption of the BMA sche those records come to be locked up each night in clinical centre, then the remaining years of my m life may be easier but they will cease to be as interest

Halifax A GARVIE

SOLDIER'S DOCTOR

SIR,—As a regimental MO myself, may I support v editorial opinion, though not for quite the same reas that the job is pleasant and beneficial, and certainl the whirlpool of apathy and boredom depicted b Jackson If the job is well done there is a ce amount of spare time How is this to be filled ? Ma McGlashan's letter in the same issue hints at the answer in learning to recognise and evaluate the "third dim sion," the cultural matrix that our patients live in, its manifestation in their own mentality

The great majority of doctors are quite incredi uncultured They do not even want to know an about Greek literature, Roman organisation, and the Jewish scriptures—the three foundations of our culture, and their ignorance is only paralleled by their inability to restrain their contempt for such immaterial factors in the ætiology of disease (A notable exception is Mr Kenneth Walker, see his "Diagnosis of Man") These hermit-crabs oscillate between the laboratory and the library, pass MD and MRCP exams at the age of 25, and at 35 produce their masterpiece, a 3-volume work on the Calcification of the Pineal Gland, the last two volumes being simply a bibliography of the previous literature

This picture is barely an exaggerated one of many of my contemporaries, men who stayed in the EMS as long as they could (often with the active connivance of their seniors) to avoid the "apathy" of Army life On the other hand, spare time can be amply filled with studying philosophy, than which there is no better mental training, or religion and mythology, or sociology and economics, for discerning the impalpable forces that guide our destinies, and so on, with time for exercise too For myself, I am finding great pleasure in studying Christian origins, and in beginning to learn Chinese

CAPTAIN RAMC (Home Forces)

SIR,—Had I not been taught in my youth to treat old age with undue reverence I might have congratulated your correspondent "Fogey," who has apparently missed the whole point of my letter, upon his choice of a non-de-plume My criticism is directed against an inflexible medico-military system which gives the regimental MO far too little medical work to do (and most of that of so trivial a nature as to be well within the compass of an intelligent boy scout) with the very natural result that he gets "browned off" (as they say) I contend that his job might very easily be made much more attractive and instructive He might, for example, be brought into much closer and more active contact—not merely as a spectator—with civil and military hospitals and civilian medical practitioners, he might with advantage be able to see the troops under his medical care through a much wider range of illness than at present, he might administer anæsthetics, perform minor operations or assist at major ones I do not in the least mind being called an immalleable brick because I doubt whether malleability is a desirable quality in bricks, and I forgive Fogey for calling me—on no evidence whatsoever—a square peg in a round hole, but to the young army doctor, with whom we are concerned, it is not the shape of the hole that matters, it is its smallness and dullnes that cramps his style I agree with "Captain RAMC" that the young MO might spend more of his spare time in acquiring general education—I mistrust the blessed word culture—but what people do with their spare time is their own affair I maintain that even the most nscientious regimental doctor at home has far too uch time on his hands which ought not to be spare , ought to be devoted to active doctoring If those in thority would provide opportunity for this, as they ndoubtedly could, there would be no need for “ pep ” lks to a much-tried generation

Crediton, Devon L N JACKSON

PRIVILEGE FOR HOSPITAL RECORDS

SIR,—The note under this heading in your issue for ay 16 (p 600) gave me the impression that the Court f Appeal had laid down some new principle of law pholding Mr C E A Bedwell’s view (with which I ubstantially agree) that hospital records ought to be rotected from disclosure to persons who contemplate ringing suit against the hospital or its staff Actually he decision did nothing of the kind, but merely followed ell-settled law

Your account of the proceedings is perfectly correct n aggrieved ex-patient, suing two surgeons and the ommittee of management for negligence, asked the ourt to grant him discovery of the relevant hospital records to assist him in building up his case Discovery of documents is asked for and granted every day in the ordinary course of litigation, the rule being broadly that a plaintiff is entitled to use documents in the possession of the other side if they are reasonably necessary to him and not protected under any special rule of procedure The question before the Court of Appeal related to two documents only a report written by the consulting surgeon to the secretary-superintendent and the letter covering it The court refused to grant discovery of this report and the letter , but not because they were confidential documents made by a member of the medical staff in the ordinary course of the hospital’s work On the contrary, the hospital’s advisers actually disclosed other confidential records to this patient on the master’s order, and did not appeal in respect of them The surgeon’s report and letter were protected for the simple reason that they were written in expectation of a claim at law The hospital claimed and were granted privilege, as you state, on the ground that these were documents passing between the committee of management, their solicitors and proposed witnesses for the defence in the action

The privilege was legal not medical The law jealously protects from disclosure all communications passing between a man and his legal adviser, on the ground that the administration of justice requires their protection , the court merely applied this rule It would be a pity if hospital managers were to believe that this decision protected all medical records from disclosure in future Such records are no more privileged than are the books of a trading company unless they happen to be prepared with litigation in view

London S W 19 D HARCOURT KITCHIN

HOSPITAL OR DOMICILIARY CONFINEMENT

SIR,—I agree with Dr Menzies in her regret at the higher proportion of bottle-fed babies among hospital cases, but I am not convinced that hospitalisation per se is to blame Owing to the shifting population in this area I cannot produce accurate figures for 1939–40 to compare with hers and I must therefore accept her 10% as representative To assess this 10% at its true value, I should like to know more of the circumstances which led these mothers to choose confinement in hospital and to make sure that they would have had a better chance of making a success of breast-feeding at home The factors which lead a woman to choose hospital may be just those which detract from breast-feeding One hears these women say “ My husband is away and I am quite alone ” . “ My mother and sisters are out all day and there is no-one to look after me ” It is not so much accommodation that is lacking as responsible friends or relatives, and it is their help which the mother needs in getting back to domestic life when she is still convalescing Without them she is liable to overtax her physical and mental abilities, and lactation suffers But why blame the hospital ? Let the health services and the relatives do their share

Selection of cases for domiciliary confinement is difficult, and the mother’s personal preference must weigh largely in deciding Until facilities for dealing with unpredictable emergencies are improved, there will be cases which have to be transferred to hospital during labour This being always to some degree detrimental to the mother, it would be unfair to deny her the right of hospital confinement if she desires it Once delivered, most women can equally well be nursed at home If, as Dr Menzies suggests, home nursing is conducive to breast feeding, some modification of our service might be made so that healthy mothers and infants are transferred early in the puerperium substituting the home for the lying-in ward Those whose home conditions are unsuitable might be prevailed upon to stay longer At present they often go home too soon, though not necessarily by the wish of the hospital staff

I am not impressed by the “ evidence that insistence on the necessity for antenatal supervision may have developed fears in the pregnant woman ” The publicity given to maternal mortality may have increased her awareness of the risks, but this sends her to the clinic where her fears are assuaged No-one suggests that the conscientious mother who attends the welfare clinic and has her child vaccinated, inoculated, immunised and weighed is abnormally fearful The same mother will seek prophylaxis for herself and her unborn child I do *not agree that hospital confinement surrounds child*-bearing with an atmosphere of abnormality The young mother accepts hospital as the normal place, just as the older generation accepted the home A happy “ normal ” atmosphere is essential, and in my experience of municipal maternity units it is uncommon to find sufficient abnormal women with “ tales of suffering ” to upset this The majority are safely through their labour and engrossed in the next stage With less selection of cases the proportion of abnormals will be less and any difficulty of this kind will disappear Some of the older multiparæ previously confined at home find they get a better rest by entering hospital, provided that their minds are at ease about their homes

Dr Menzies is right in pointing out the deficiencies in the breast-feeding results of hospital mothers Nevertheless I still think that for the majority of mothers of the artisan class the advantages of institutional midwifery outweigh its disadvantages.

St Andrew s Hospital, E 3 A BARBARA FIELD

DOSAGE OF LOCAL ANÆSTHETICS

SIR,—Professor Macintosh and Dr Bannister, in their letter of July 18, reprove me for suggesting unnecessarily large doses of ‘ Percaine We are, of course, talking of two different things—the maximum permissible dose and the minimum effective dose after which we should strive I have not found the maximum dose of percaine stated in any textbook nor is there an adequate account of the treatment of overdosage It is a fact that a number of anæsthetists and surgeons in London had previously accepted 150 c cm of 1 1000 percaine as a safe dose An anæsthetist of exceptionally wide experience has recently told me of patients with jaundice and of one woman weighing only 4½ stone, all of whom had the full 150 c cm without ill effect There is no account in the published work of convulsions occurring in patients who had had percaine alone It has been suggested that the convulsions are due to asphyxia This is not improbable in the first case I described , the second two had nitrous oxide and oxygen in routine proportions and their breathing was not unusually shallow

Since meeting with these cases I have used considerably smaller doses than the maximum I suggested, but my impression has been that they have not been quite so effective A subcostal block takes a large quantity of anæsthetic , many prefer an intercostal block which can be effected with some 70–80 c cm Nerve block for laryngectomy is not really comparable, and there can be few anæsthetists fortunate enough to have seen a sufficient number of cases to elaborate a routine method of anæsthesia

Dr Clendon (Aug 1) raises the question of delayed detoxication from liver damage We do not know that the liver is the only, or even the most important, site of detoxication of percaine Recent work suggests that in some of the barbiturates the liver is not essential for this purpose (Schiefley, C H and Higgins, G M *Amer J med Sci* 1940, 200, 264 Kohn Richards, R and Appel, M *Anesth. & Analges* 1941, 20, 64) In my

The following diplomas were granted jointly with the Royal College of Physicians

DOMS —Margaret L Clay, K D Foggitt, S S Freedman, D P Gurd H E Hobbs, M B Longinotto, W T C Lumley, G O M Neatby, R L Richards, and P M Wood

DMR —F H Bonnell, G C D Evans, R C M Hadden, H J Johnson, Margaret D Snelling, and J H Stranger

The honorary medal of the college has been awarded to Lord Nuffield in recognition of his service in "assisting the improvement of natural knowledge and of the healing art and of his many liberal acts and distinguished labours inspired by the desire to advance the science and practice of medicine and surgery" The medal was instituted 140 years ago and this is the nineteenth occasion on which it has been awarded

D T M & H

The committee of management of the Conjoint Board have decided to discontinue the examinations for the diploma in tropical medicine and hygiene until further notice

King Edward's Hospital Fund

In the last year the Fund has distributed £320,000, and receipts were over £280,000 Since its foundation the fund has distributed over ten million pounds

Medical Superintendents' Society

A meeting of the executive committee will be held at the Midland Station Hotel, Derby, on Saturday, Aug 15, at 2 15 PM

Awards for Nursing

Over 10,000 members of the Civil Nursing Reserve have now earned good service awards A number have also qualified for the special award presented to those who have given service in nursing patients suffering from tuberculosis or infectious diseases The reserve now has over 28,000 members in whole time employment and 18,000 in part time

Army Dental Service

Colonel A B Austin has been appointed director of the Army Dental Service, in succession to Major General D Clewer, who retires on Aug 31

High-frequency Apparatus

The Home Office has relaxed the order forbidding any person from possessing or using a high frequency apparatus with an output of over 10 watts except under permit from the Post master General Hitherto permits have only been issued to hospitals and similar institutions, but under the new order any person, including aliens, may apply to the Postmaster General for a permit, which will not, however, be issued until the applicant has installed a screen and mains filter in accordance with Post Office specifications Applications should be addressed to the Engineer in Chief, Radio Branch (W 2/8), General Post Office, Harrogate, Yorkshire, who will also give particulars of the screening required

Medical Casualties

The following casualties have been announced

Died of Wounds —Surgeon Commander James Michael McNamara, MB NUI, HMS *Hermes*

Missing presumed killed —P/T/Surgeon Lieutenant J D James, MRCS, RNVR, MHS *Belmont*

Prisoners of War —WS/Captain W G H Allen, MD Durh, T/Major J D Fraser, MD Glasg Major G F Harrison, MB Lond, Major J H Prain, MB St And, WS/Captain A C P D Thomson, MB Edin, Lieutenant J W Anderson, FRCSE, T/Major J D A Gray, MB Edin, Captain A F Hutchison, MB Durh, WS/Captain J A MacLeod, MB Glasg, T/Major O G Prosser, MB Aberd, Lieut Colonel J K Steel, and T/Surgeon Lieutenant R St C Mooney, MB Dubl, RNVR, HMS *Bedouin*

Missing —Major J A G Carmichael, MRCS, and Captain Geoffrey Lancaster, MB Manch (in the Middle East), and Surgeon Lieutenant J G Reed, MRCS, RNVR (after the evacuation of Singapore)

Dr Elsie Crowe is now officially presumed a prisoner of war in Sumatra

Medical Honours

The George Medal has been awarded to Squadron Leader Frank George Mogg, M R C S, Auxiliary Air Force

One night in May an aircraft crashed on the edge of an aerodrome and immediately burst into flames Three members of the crew were thrown clear of the wreckage and killed, a fourth managed to extricate himself from the tail turret A wireless operator was, however, trapped in the blazing fuselage, and Squadron Leader Mogg, clad only in overalls over his pyjamas, went into the blazing wreckage to rescue him The aircraftman who accompanied Mogg lay on the floor and using a greatcoat as a shield was able to afford some protection while he administered morphia to the injured operator During the time the officer and airman were working in the wreckage two oxygen bottles exploded within a few feet of their heads and there was grave danger that others might have done so at any time Squadron Leader Mogg was badly scorched and sustained burns to his hands and wrists, but he accompanied the dying wireless operator by ambulance to hospital some six miles away He then fainted and had to receive medical attention

The DSC has been awarded to T/Surgeon Lieutenant G P Fahrni, MD, RCNVR, for great bravery and devotion to duty

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

Appointments

SMITH A H D, MB EDIN, consulting surgeon to the Llanelly District General Hospital

The following examining factory surgeons have been appointed —

- STEPHEN, J H, MB ABERD Thame, Oxfordshire,
- GRAY, A P, MB ABERD Wingate, Durham,
- THOMPSON HILL, W A, MRCS Llanrwst, Denbigh,
- KIDD, J L MB GLASG Belshill Lanark,
- COOPER, J D, BA CAMB, MRCS Princes Risborough, Bucks, and
- MITCHESON, G F L, BM OXFD Shoreham, Sussex

Colonial Medical Service —The following appointments are announced —

- GUTHRIE, J P MRCS MO, Kenya
- LUCEY, J F, MB CAMB MO, Tanganyika Territory
- MICHIE, CHARLES, MB ABERD MO, Sierra Leone
- DE BOER, H S, MRCS, DPH, DTM & H DMS, Uganda, and
- PATTON, W H G, MB LPOOL MO, Kenya

Births, Marriages and Deaths

BIRTHS

HARDIE —On Aug 3, at Great Malvern, the wife of Captain A W Hardie, RAMC—a son

HUTSON —On Aug 4, at Newcastle on Tyne, the wife of Captain C S M Hutson RAMC—a daughter

SLOAN —On July 26, at Landour Mussoorie India, the wife of Lieutenant T B M Sloan, IMS—a daughter

STRANGE —On Aug 4, at Newcastle on Tyne, the wife of Mr F G St Clair Strange, FRCS—a son

MARRIAGES

GUILD—INNES —On Aug 5 in London, William John Forbes Guild, FRCSE, surgeon lieut commander RN, to Joan Elisabeth Innes

HILL—CUMMING —On March 20, in Lagos, Thomas Rowland Hill major RAMC, to Janet Sybil Cumming

DEATHS

GRANGER —On Aug 4 at Exmouth, Thomas Arthur Granger, CMG, MB EDIN, colonel IMS, retd

JERRARD —On Aug 7, in Exeter, John Henry Frederick Jerrard, MB CAMB of Honiton, Devon

THOMPSON —On Aug 4, James Thompson, MC, MB EDIN, FRCSE, JP, of Devizes, aged 47

VERNON DAVIES —On Aug 4, at Tunbridge Wells Arthur Vernon Davies, OBE, MB MANC, MP for Royton (Lancs) 1924–31, aged 70

LOCAL TREATMENT OF INFECTED WOUNDS WITH SULPHATHIAZOLE

H N GREEN
M A CAMB, M D, M SC SHEFF
PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF SHEFFIELD

T PARKIN
M B EDIN
CLINICAL ASSISTANT ROYAL INFIRMARY, SHEFFIELD

IN spite of the wide use of sulphonamides locally, either prophylactically or in the treatment of established infection, the value of the treatment is still not accurately known and widely different opinions are regularly expressed (see *Lancet* 1942) Many seem to think, largely on the basis of results with virulent animal infections, that it is of great value in prophylaxis but has no place as a curative measure The difficulties of assessing its value are considerable and a final assessment may only be obtained from a statistical analysis of a very large number of comparable wounds Nevertheless, to discount this treatment altogether, as some do, suggests that a lack of knowledge of the mode of action of the sulphonamides is still very general among clinical observers

It is essential to recognise that these drugs have a direct antibacterial action and that their curative action is due entirely to this, and not to any indirect action on the body tissues generally The most important proof of this was the finding by Woods (1940) that *p*-aminobenzoic acid antagonised the action of sulphanilamide Fildes (1940) postulated that the sulphonamides act by blocking the enzyme concerned in the further utilisation of *p*-aminobenzoic acid in the bacterial cell This theory has received much experimental support from several workers, including Green and Bielschowsky (1942) The latter workers showed that the sulphonamide itself, and not some derivative of it, is most probably the active substance, and that the ether-soluble anti-sulphanilamide substance in bacteria is almost certainly *p*-aminobenzoic acid The demonstration of its mode of action is the most conclusive evidence of its purely direct effect, but the following facts (there is no space to discuss the now extensive literature) give additional support to it (1) Sulphonamides are effective in synthetic media (i e, in the absence of tissue extracts) (2) Their in-vitro activity in most instances parallels that in vivo (3) Numerous investigations have shown that they have no effect on the cellular or humoral defence processes of the body (4) Local treatment of experimental wounds is effective against many types of infection, both prophylactically and curatively From the experimental standpoint, therefore, there is every reason for expecting the sulphonamides to be efficient local bacteriostatic agents in human infections

TABLE I—DIMINISHING INHIBITORY EFFECT OF *p* AMINOBENZOIC ACID ON SULPHANILAMIDE, SULPHAPYRIDINE AND SULPHATHIAZOLE DEMONSTRATED IN INOCULUM OF *Brucella paramelitensis*, 2×10^4 COCCI PER ML

*p*AA (mg per 100 c.cm)	Percentage of incident light absorbed at 48 hr		
	Sulphanilamide 1/1000	Sulphapyridine 1/1000	Sulphathiazole 1/1000
0	0 (4)	0 (4)	0 (∝)
20	52	36	0 (4)
2	48	40	0 (5)
0 2	52	40	0 (12)
0 02	59	35	0 (∝)
0 002	48	17	0 (∝)
Broth controls	51	46	48

Figures in parentheses indicate number of days at which turbidity first appeared. *p*AA = *p* aminobenzoic acid

Another widely held and fallacious view is that the different sulphonamides are specific for certain bacterial species The fact is that the bacteriostatic effect on any species is directly related to the capacity of the compound to block the enzyme whose substrate is *p*-aminobenzoic acid Sulphanilamide, sulphapyridine and sulphathiazole require increasing amounts of *p*-aminobenzoic acid to antagonise them (see table I) and the increase is proportionately the same whatever the test organism Quantitative studies on a number of organisms show that the amounts required are in the order of roughly 1 5 50 and the ratios of the bacteriostatic potencies of the three compounds is of roughly the same order with comparatively small variations for different organisms These variations are due to the action of the heterocyclic half of the molecule of sulphapyridine and sulphathiazole (e g, the thiazole group on staphylococci) which gives them a more selective action on certain bacteria It must be stressed that from the clinical aspect these differences in species susceptibility are relatively unimportant At similar concentrations the ratio of the bacteriostatic powers of sulphathiazole and sulphanilamide is roughly 50 with *Staphylococcus aureus* and yet the ratio is only reduced to 25 with *Bacterium coli*, an organism which is much more sensitive to sulphonamides in general In other words, sulphathiazole is the sulphonamide of choice in staphylococcal (and any other type not highly sensitive to sulphanilamide) infections mainly because it is the most effective sulphonamide generally available in this country

The therapeutic effect of these compounds when given by mouth is modified by their rate of absorption, but in local use the modifying factor is their solubility in the tissue fluids The much greater solubility of sulphanilamide (cir 1/70) as compared with sulphathiazole (cir 1/700) possibly wholly offsets its weaker bacteriostatic action since the ratio, $\frac{\text{sulphonamide concentration}}{\text{no of bacteria killed}}$, falls rapidly with increasing concentration of the drug (Green 1940) The period for which the bacteria are exposed to a saturated solution is, however, a more important factor than the solubility of the compounds, if their in-vitro potencies at saturation levels are not widely different Bacteria, if still viable, rapidly recover from sulphonamide inhibition, so that the optimal effect is obtained by maintaining a high concentration continuously until most of the bacteria are killed directly by the drug or by phagocytosis Under these conditions, provided complete access can be obtained, local treatment ought to be more effective than general, for, given orally or parenterally, the concentration of sulphathiazole in the infected area will not be more and may be very much less than a tenth of that reached after local application A high local concentration is also often essential, since many bacteria (e g, *Staph aureus, Bact coli*) which are relatively insensitive at the concentration reached in the blood (say 1/10,000) are quite sensitive to a much higher concentration (say 1/1000) It is important, in fact, to recognise that all bacteria are sensitive in some degree to the bacteriostatic action of the sulphonamides, though in some instances (e g, *Pseudomonas pyocyanea*, *Bacillus subtilis*) the concentration must approach saturation point before the effect is really significant

Another very real advantage of local treatment is that the danger of toxic effects is slight Even with continuous application to large, infected wounds the blood concentration in our series did not rise much above 2 mg per 100 c cm and it was usually below 1 mg The hazards of systemic sulphonamide treatment, in particular the renal complications, are thus obviated

OBJECTIONS TO LOCAL APPLICATION

The optimal conditions for sulphonamide therapy—i e, a continuous high concentration without systemic damage—ought to be attained by local application What are the objections? They may be briefly classified as follows

(1) Pus and tissue exudates have an anti-sulphonamide action This is due to anti-sulphonamide factors (probably chiefly *p*-aminobenzoic acid) released from bacteria and also from digested tissues, the amount supplied by each is not known and will vary with the type of bacteria and the degree of tissue destruction This is probably the main factor tending to prevent the antibacterial effect of the sulphonamides, but the same antagonism must play a part when the drug reaches the area via the blood-stream, though possibly not to the same extent On the other hand, the higher concentration of the compound attained in local treatment demands a proportionately greater amount of anti-sulphonamide factor to neutralise its effect, and, if the infected area is kept as free from exudate as possible by

thorough removal before each treatment, the clinical results suggest that this anti-sulphonamide action is not usually sufficient to completely neutralise the effect of the sulphonamide Provided that even slight bacteriostasis is achieved, the diminishing number of bacteria will cause a reduction in the supply of anti-sulphonamide factor from both bacteria and tissues, and, so long as continuous saturation is maintained, progressive improvement must occur once the balance has changed in favour of sulphonamide If pus formation is excessive and an early response to treatment does not occur, repeated cleansing, with fresh applications of the powder, is necessary until the local infection shows signs of subsiding In our series of cases obvious improvement usually set in in the first few days Failure is probably often due to a lack of persistence in treatment in the initial stages when an excessive amount of anti-sulphonamide factor is preventing rapid bacterial destruction

(2) The sulphonamides are absorbed from the local site, and in the case of the most soluble compound, sulphanilamide, this absorption is rapid Viable organisms will then rapidly multiply again and it is theoretically possible that the renewed growth may be greater than the normal, for there is some evidence that very low concentrations of the sulphonamides may have a growth-stimulating action on bacteria (Green 1940, Green and Bielschowsky 1942) This objection applies particularly to the prophylactic treatment of sutured or very deep wounds, and failure in these cases could be due to lack of complete sterilisation, before, or a fresh infection from the blood-stream after, the drug has been absorbed. Theoretically prophylactic treatment should aim at using the largest possible quantities of the drug, with a preference for the more insoluble compound, but recent work (see *Lancet* 1942) suggests certain dangers in this method In already infected wounds treatment should never allow of a period in which a surface film of powder is not present

(3) Local damage to the tissues by a saturated sulphonamide solution is a theoretical danger Actually, it would appear to be insignificant compared with the effect of other antiseptics Glynn (1941) has shown in rabbit granulation tissue that a barely significant inhibition of fibroblast proliferation is produced by sulphathiazole and sulphapyridine, but not by sulphanilamide Sulphathiazole has no toxic action on striped muscle, whereas sulphanilamide and sulphapyridine have a slight but definite one. Tissue-culture work and our own experience with animals and man indicate that they are comparatively harmless compounds to the tissues

(4) The development of resistant strains of bacteria is probably a real danger, but here again the danger should be less with local than with systemic treatment Strongly resistant strains only arise if viable bacteria are exposed to sulphonamides for a few weeks, but the resistance increases progressively from the time of initial exposure (Green 1940) The chance of this complication arising is much diminished if a continuous saturation with the drug is maintained from the start, thereby rapidly reducing the number of the pathogenic organisms present Intermittent or spasmodic treatment will favour the development of these resistant organisms An important point is that resistance to sulphathiazole is less easily developed than to either sulphanilamide or sulphapyridine One of us (H. N. G) has found that it was impossible, with the strain of *Bact coli* used, to produce by "training" in sulphathiazole a strain significantly resistant to sulphathiazole, though it became strongly resistant to sulphanilamide Preliminary observations with other bacteria suggest that resistance is less easily developed with sulphathiazole than with sulphapyridine or sulphanilamide Sesler and Schmidt (1942) report a similar finding with the pneumococcus This property of sulphathiazole may well be one of the main factors in its greater therapeutic effect

(5) Hawking (1941a) has shown that a sulphonamide applied locally penetrates only a few millimetres into the infected tissue and therefore may not reach viable bacteria, which nevertheless are accessible via the blood-stream It seems probable, however, that provided the bacteria in the necrotic tissue and exudate, which is the actual culture medium, are destroyed, the deeper granulating zone with its known capacity for combating infection is easily capable of overcoming the deeper residual infection The rapid development of healthy granulation tissue actually observed during this treatment suggests that the reduction in toxin production in the surface exudate allows this tissue to rapidly assume its normal protective function

The balance of experimental evidence is strongly in favour of using local treatment in localised infections Only in this way in the presence of infection can a concentration be attained which is likely to be lethal to the hæmolytic streptococcus, pneumococcus and Neisseriæ, and strongly inhibitory to *Bact coli*, *Staph aureus* and even to *B proteus* and *Ps pyocyanea* Of the sulphonamides at our disposal, sulphathiazole, for the reasons given, was used in the clinical trials, of which a condensed account now follows

CLINICAL TRIALS

Methods —The wound was gently swabbed free of pus and loose debris using gauze soaked in normal saline , it was then gently dried with dry gauze Sulphathiazole powder, which was not sterilised (an error now rectified) was sprinkled from a sterile container, covered with one layer of gauze, over the surface to form a layer roughly $\frac{1}{8}$ in thick Any pockets or undermined edges were carefully filled from a small sterile spatula When deep pockets or undermined areas existed an insufflator was used It was then covered with several layers of dry gauze and finally with a square of gamgee tissue In plaster cases with a "window" a firm bandage was applied to counteract "window œdema" The treatment was repeated every 2, 3 or 4 days, the aim being to maintain a continuous layer of powder in contact with the wound It should be specially noted that the treatment was not stopped when signs of infection had disappeared but was continued, where possible, until wound healing was completed Each treatment was carried out by one of us personally, a point of possible significance in the results obtained Swabs from infected areas were cultured on solid and liquid media, with and without *p* aminobenzoic acid (0 2 mg per 100 c cm)

For reasons of space detailed records of only 4 of the 16 cases are given * They illustrate the effect of the treatment on three types of bacterial infection, but otherwise were chosen arbitrarily The main features of all the cases are summarised in table II

CASE 1 —A man aged 38 was struck on the left leg by a steel bar Examination revealed an irregular flesh wound extending from the external condyle of the femur to the junction of the upper and middle third of the leg There was a compound fracture of the tibia and fibula The wound was excised and sutured after inserting 'Vaseline' packs and a rubber drain, and the fracture was reduced and immobilised in plaster The next day the temperature rose and sulphapyridine, 6 g daily, was given by mouth for the next 14 days On the 16th day after injury the packs were removed from the wound, which was found to be grossly infected and discharging pus copiously He was still feverish and sulphapyridine in the same dosage was given for a further week A month after the injury the wound was still grossly infected and the knee joint was swollen From this time the wound improved very slowly and 10 weeks after the injury the temperature settled He was discharged after 12 weeks in hospital with the leg in plaster, with a window for continuation of the acriflavine dressings which had now been applied for some weeks

He was referred to us for treatment 22 weeks after the injury There was a longitudinal wound, 6 in × 2 in and $\frac{1}{2}$ in deep, over the upper end of the tibia The wound was grossly infected with a free purulent discharge and with no sign of attempted healing , there were several sinuses leading down to the ununited fracture There was slight fever (99°–100° F). Cultures of the pus showed *Staph aureus* and *B proteus* Local treatment with sulphathiazole was begun The wound was thoroughly cleaned and final traces of exudate removed with saline swabs followed by the application of 4 g of the powder, distributed uniformly over the surface When the wound was examined 4 days later obvious healing was in progress , the amount of pus was much reduced and healthy granulations were evident at many points The wound was again treated with the powder (5 g) Nine days after beginning the treatment the wound was quite clean with abundant granulations covering it and commencing epithelial growth at the edges , the bacterial flora remained unchanged

---

* The detailed records of all the remaining cases and some photographs may be seen at the Medical Research Council Offices, School of Hygiene and Tropical Medicine, London A limited number of copies of the case records are available from the same source for research workers

TABLE II—INFECTED WOUNDS TREATED LOCALLY WITH SULPHATHIAZOLE

Case no	Age (yr)	Injury	Surface wound	Time infected before treatment (days)	Initial treatment	Causal bacteria	Elimination of causal bacteria (days)	Total sulphathiazole (g)	Surface infection (days)		Remarks
									Subsiding	Absent	
1	38	Comp fract. tib and fib	6 in × 2 in Sinuses present	152	Acriflavine; sulphapyridine (126 g. orally)	*Staph aureus*	N	21	5	15	Wound healed 28th day of treatment except for few small sinuses See case history
2	57	Laparotomy wound	5 in. × 4 in	18	Sulphanil- (16 g. orally)	*Strep hæmolyticus*	11	15	3	15	Uninterrupted healing of wound
3	51	Comp fract. tib and fib	3 in. diameter,	21	Winnett Orr	*Staph aureus*	N	18	2	13	Surface wound healed, after removing loose sequestrum, by 37th day of treatment.
4	18	Comp fract femur simple fract. tib and fib	Supracondylar thigh amputation	5* 19†	Sulphanilamide (28 g orally)	*Strep hæmolyticus ; Staph aureus*	N	45	4	15	At initial operation and at thigh amputation wounds packed with sulphanilamide See case-history
5	33	Fract. tib and lacerated calf	Guillotine amputation at mid thigh	4	Sulphapyridine (40 g orally), AGGS	*Cl welchii*, *Staph aureus*	23	22	13	23	Oral sulphapyridine for 6 days after local treatment began Wound packed with sulphanilamide at time of amputation Healed 46th day of local treatment
6	30	Comp fract. tib and fib	Guillotine amputation at mid-thigh	17	Winnett Orr sulphapyridine (72 g orally)	*Staph. aureus*, *Cl sporogenes*	7	15	3	7	Initial excised wound and amputation wound packed with sulphanilamide at time of operation
7	62	Arthrodesis of knee-joint	Guillotine amputation at mid thigh	65	Sulphapyridine (159 g orally), acriflavine	*Staph aureus*	N	30	7	14	Uninterrupted recovery Wound healed by 28th day
8	18	Comp fract femur	Guillotine amputation at mid thigh	60	Sodium sulphapyridine sulphapyridine orally , eusol, acriflavine	*Strep hæmolyticus*	N	30	3	18	Wound healed by 50th day
9	47	Shrapnel wound of wrist	Dorsum of wrist, 2 in diameter	8	Acriflavine, sulphapyridine (28 g. orally)	*Staph aureus*	N	3	1	5	
10	34	Fract. phalanx-lacerated wound	Whole of finger	28	Winnett Orr, acriflavine	Probably *Staph. aureus*	N	6	2	7	Amputation of stiff finger
11	40	Comp fract. tib and fib	2 in × 3 in	105	Winnett Orr cod-liver oil dressings	*Staph aureus*	N	13	2	12	Initial injury 4½ yr ago with recurrent infection Uninterrupted healing of wound with 16 days treatment
12	23	Third-degree burn of foot	Nearly half dorsum of foot	19	Gentian violet, cod-liver oil dressings	*Ps pyocyanea*	23	20	1	19	See case history
13	55	Traumatic amputation of lower legs	Amputation below L. knee	20	Sulphapyridine (36 g orally)	*Staph aureus*	N	60 (sulphanilamide)	8	18	Both amputation wounds packed with sulphanilamide at time of operation Amputation stump on R leg was much less severely infected treated with acriflavine Skin graft on L at 20 days, healed a month later
14	13	Excision of chondroma of scapula	5 in × 2 in.	12	Open drainage	*Staph albus* (pathogenic)	N	9	2	14	See case-history
15	44	Open reduction of fract. spine	8 in × 1 in	10	Sulphapyridine (34 g. orally)	*Staph albus* (pathogenic)	N	8	2	8	Sulphathiazole given orally 2nd to 5th day of local treatment Wound completely healed by 10th day

N = Not sterile while open wound still present.
AGGS = Anti gas gangrene serum.

* After final amputation
† After first operation wound.

A further 4 g of the powder was applied and 4 days later a few small sequestra near the surface were removed. By the 15th day of treatment the whole surface of the wound was covered with epithelium except for the openings of a few small sinuses which were not discharging More powder (4 g) was applied and the treatment repeated on the 19th day. By the 28th day the wound was soundly healed except for the small sinus openings; the fractures were united From now on the sinuses occasionally discharged a little pus from which *Staph aureus* was grown. He was discharged after 7 weeks in hospital with the leg in a fresh plaster. When seen 3 weeks later the wound still remained soundly healed but the skin was reddened from the irritation of small amounts of pus coming from the sinuses.

He was admitted at intervals for the removal of small superficial pieces of necrotic bone. At the present time (a year later) there is still a little discharge from one sinus, but the wound remains healed.

CASE 4.—A youth aged 18 was riding a motor cycle when he collided with a tramcar and sustained a compound fracture of the right femur, in the lower third and a simple fracture in the middle of the right tibia and fibula A portion of the femur protruded through a 4 in. longitudinal wound commencing 3 in. above the knee on the medial aspect The wound was excised and sutured after packing with sulphanilamide powder, the fractures reduced, and the whole limb immobilised in plaster The temperature rose immediately after the operation to 100° F., and sulphanilamide, 4 g daily, was given by mouth for a week, but the temperature continued fluctuating between 99° F. and 102° F. His general condition was poor The day after the operation the thigh showed considerable œdema, the foot was cold and pale and without arterial pulsation The plaster was split but the foot showed no sign of returning viability and on the 6th day the lower leg was amputated 5 in below the knee joint and a blood transfusion given Signs of infection in the stump became obvious on the 9th day after injury and the knee joint was distended with fluid The temperature was now rising to 103° F and on the 14th day there was a secondary hæmorrhage from the stump This was treated effectively and a further transfusion of whole blood given On the 15th day a further hæmorrhage occurred and since the stump was grossly infected a re amputation was done 3 in above the femoral condyles, the wound packed with sulphanilamide and the flaps left unsutured Pyrexia (100° F) continued and by the 20th day after the injury the stump wound and flaps were covered with pus and discharging profusely Cultures grew *Streptococcus hæmolyticus*, *Staph aureus* and *B proteus*

Local treatment with sulphathiazole was begun 5 days after the amputation and 20 days after the original injury, 10 g was needed to cover the infected area completely A further 11 g was applied 4 days later, and 6 hours after the application the blood sulphathiazole (total) was 0 35 mg per 100 c cm and after 24 hours 0 8 mg per 100 c cm Further applications of 10, 5, 5, 2 5 and 2 g were made on the 6th, 9th, 15th, 22nd and 28th days of treatment Blood sulphathiazole values on the 7th, 10th and 16th days were 0 25, 2 2 and 1 6 mg per 100 c cm By the 6th day of treatment the temperature was normal and the wound was granulating freely and much cleaner, showing only specks of pus in small pockets, cultures from which grew *Staph aureus* and *B proteus* Rapid improvement was maintained and by the 15th day the wound was quite clean and covered with thick granulation tissue In spite of the absence of clinical infection, *Strep hæmolyticus* and *Staph aureus* were grown from a swab of the wound surface The *Strep hæmolyticus* now showed an increased in vitro resistance to sulphanilamide but not to sulphathiazole By the 19th day of treatment the wound edges were rapidly drawing in, and, though there was no obvious suppuration, culture grew *Ps pyocyanea* and a few colonies of *Staph aureus* On the 29th day a few colonies of *Strep hæmolyticus* only were grown from the wound swab The wound area continued to diminish and on the 38th day an operation was performed to reconstitute a weight bearing stump The surgical wound remained healthy but still grew a few *Strep hæmolyticus*, and on the 8th day after this final operation it broke down slightly and discharged a little pus from which *Strep hæmolyticus* in pure culture was grown The wound healed again in a few days after two applications of sulphathiazole and when last seen the patient was waiting to have an artificial limb fitted

Case 12 —A man aged 23 sustained a third degree burn of his left foot when a hot bar fell across his boots Blue dye (probably gentian violet) was applied to the burn at work and he then attended the hospital casualty department where it was dressed daily with cod liver oil for 23 days

Owing to complete lack of healing and increasing signs of local infection he was admitted to hospital on the 24th day after injury There were gangrenous patches on the dorsum of the 2nd and 3rd toes and half the great toe, and a sloughing, severely infected ulcer over a third of the dorsum of the foot with the extensor tendons visible in the purulent exudate at its base Cultures grew a profuse growth of *Ps pyocyanea* and also colonies of *Staph aureus* The area was cleaned and 5 g of sulphathiazole applied After 2 days treatment the wound was much cleaner, now only speckled with pus, and a portion of the gangrenous tissue on the great toe was separating Cultures grew *Ps pyocyanea* and a few colonies of non-hæmolytic streptococci Sulphathiazole (5 g) was again applied By the 6th day granulation tissue could be seen at the wound edges and the necrotic tissue had separated further The wound, though healing, still showed suppurating foci from which *Ps pyocyanea* and *Staph aureus* were grown The infected area was again covered with sulphathiazole By the 10th day the improvement was striking, the whole wound, with the exception of the toes where gangrenous tissue was still separating, was covered by very vascular granulation tissue It was treated with sulphathiazole and again on the 15th day and 19th day On the latter date there was no sign of sepsis, and swabs on this and the following day were sterile On the 23rd day slight epithelial growth could be seen at the wound edges and the gangrenous tissue had completely separated The wound remained clean but epithelial growth was very slow, so that on the 40th day a skin graft was performed with good result A month later the foot was quite healed and later the useless 2nd, 3rd and 4th toes were amputated

Case 14 —A girl aged 13 was admitted to hospital for excision of a chondroma of the inferior angle of the right scapula The tumour, about 1 in in diameter, along with the inferior angle of the scapula, was removed The next day the temperature rose and fluctuated between 98° F and 100 5° F for the following 3 days On the 4th day after operation the wound was tense and bulging, with beads of pus exuding from it The tense sutures were removed and the gaping wound discharged pus profusely The temperature fell to normal for a day or two but rose to 101° F on the 9th day when the wound was suppurating still more freely A pure culture of *Staph albus* (coagulase positive) was grown from the pus

On the 12th day after operation there was an elliptical wound, 5 in long and 2 in wide and about 1 in deep, covering the vertebral border of the scapula, it was covered with a thick purulent exudate It was cleaned and packed lightly with sulphathiazole (2 g) The temperature fell to normal the same day and remained there By the 2nd day of treatment the wound was already much cleaner A further application of 2 g of sulphathiazole was made and the treatment was repeated every 2 days until the 14th day On the 4th day suppuration had practically ceased and signs of healing were present at the upper and lower poles The wound continued to heal rapidly and by the 11th day it was bridged across at its widest part by a band of granulation tissue largely covered with epithelium *Staph albus* (coagulate positive) in pure culture could still be grown Progress was uninterrupted from now on and by the 14th day there was no sign of clinical infection There was an exuberant growth of granulation tissue which appeared to prevent complete epithelialisation However, after occasional cauterisation with silver nitrate, the wound was completely epithelialised by the 24th day The patient was discharged 28 days after operation with the wound completely healed

ANALYSIS OF CASE-HISTORIES AND FINDINGS

At the start we intended to treat only those infected wounds which had shown no improvement with other treatments over a long period It was however impossible to find sufficient cases of this kind and there are only 4 out of 15 (cases 1, 7, 8 and 11) which were of very long duration In 6 the infection persisted without improvement for periods of 17–28 days and the remaining 5 were of from 4 to 12 days' duration The main factors in the choice were that the wound should be large, severely infected and showing no signs of response to the prescribed treatment Up to the time of beginning local sulphathiazole we had no responsibility for the treatment A fair number of small infected lesions such as boils, bed sores, &c were also treated with excellent results but we have only included wounds so severely infected that a rapid response to treatment would be of possible therapeutic significance

In every case the infection had been treated by other methods before the local application of sulphonamide Local treatments included immobilisation in plaster, fomentations, antiseptics, cod-liver oil dressings, and combinations of these The majority (10 out of 15) had received oral or intravenous sulphonamide, usually in full doses In 2 only (cases 10 and 15) this was continued for a few days after the local sulphonamide treatment was started Signs of systemic infection usually abated but the local infection persisted or even developed in spite of the oral treatment In some instances (cases 3, 4, 5, 6 and 13) the operation wound, which was not clinically infected at the time, was packed with sulphanilamide It would appear that a single prophylactic application, at any rate in a patient infected elsewhere, may be useless, and under these conditions vigorous local treatment should be continued, if possible, until definite signs of healing appear

It was hoped to find comparable infected wounds in the same person, one of which could be used for a control treatment, but the difficulties are great, as is illustrated by the only possible case (13) in this series Two below knee amputation stumps were infected but one wound was much more extensive and much more severely infected, and showed a much heavier growth of *Staph aureus* than the other It was impossible accurately to assess the value of two treatments under such conditions It should be noted that, in this one case, sulphanilamide instead of sulphathiazole (owing to a tempora page in supplies) was used and our impression was that the response was not so impressive as in similar cases treated with sulphathiazole Another severely infected (anaerobic streptococcus) amputation stump, not included in this series, also rapidly responded to sulphathiazole after a very slow response to 2 weeks' treatment with sulphanilamide

Wound cultures were made at short intervals immediately before the application of sulphonamide Although duplicate cultures were made in media containing *p*-aminobenzoic acid, the same types of bacteria were always grown in both cultures Care was taken not to grossly contaminate the swab with sulphonamide and it seems that the small amounts occasionally conveyed to the media were never sufficient to inhibit growth

In only 4 of 15 cases did the organism considered to be primarily responsible for the infection disappear completely during the course of treatment (see table II) A pathogenic staphylococcus was the commonest primary infecting organism in this series (10 of 15), and in only one instance (case 6), did the treatment apparently result in the destruction of all the organisms present Bacteriological evidence of infection continued until the wound healed in 2 out of the 3 cases (2, 4 and 8) infected with the *Strep hæmolyticus* In both instances in-vitro tests showed that they were somewhat more resistant to the action of sulphanilamide, but only slightly, if at all, more resistant to sulphathiazole 14 days after the treatment was begun In the single cases in which *Clostridium welchii* (5) and *Ps pyocyanea* (12) were considered to be the primary infecting agents the organisms could no longer be grown after 23 days treatment No wound became completely free of potential pathogens until healing was in an advanced stage

There was no obvious relationship in the early stages of treatment between the amount of growth on plate cultures and the rate of decline in signs of clinical infection When signs of infection had mainly disappeared the plate growths were usually not so heavy, but they gave little information about the related clinical condition This was obviously due to the crudity of the method, and if accurate bacterial counts on a wound surface were possible there is little doubt that they would show a progressive diminution during treatment The ordinary routine methods of culture are of little value for assessing progress, and from the clinical standpoint numerous cultures are a waste of effort On the other hand, if the clinical infection fails to subside under treatment in-vitro tests of the resistance of the infecting organism to the sulphonamide used as compared with that when first isolated, should be of real value in deciding whether to change the form of treatment If the resistance was high, another sulphonamide to which the resistance of the strain was shown to be less, or better, one of the new "biological" antiseptics, should be used No occasion for this change occurred in any case in our series

Determinations of the blood sulphonamide content were not made in all the patients, since it is already well established (Hawking 1941) that the figure never rises very high compared with that following oral administration in adequate amounts The maximum concentrations reached ranged between roughly 1 and 2 mg per 100 c cm (see case 4 report) The rate at which sulphathiazole is absorbed from the wound is not rapid enough to produce high blood levels This no doubt accounts for the fact that not one patient showed any toxic symptoms When it is appreciated that the amount of sulphonamide absorbed was usually less and rarely more than 1 g per day, this finding is not unexpected

Two noteworthy features in the healing process were considered to be related to the treatment First, there was a tendency in many cases to capillary hæmorrhage at the edges of the wound The bleeding was sometimes sufficient to suggest a secondary hæmorrhage but no large vessel was involved though it was sometimes necessary to insert a suture Secondly, the formation of granulation tissue often seemed to be exuberant and in some instances the tissue projected well above the surface of the wound It seemed to us that the presence of sulphathiazole was responsible for this excessive growth of highly vascular granulation tissue, which bled very easily and in a few wounds appeared to hinder epithelial growth In cases 12 and 13 it was necessary to complete healing by skin grafting, it was noteworthy how quickly the graft took and healed Mellon, McKinney and Rack (1942) found that sulphathiazole stimulated tissue-culture growth, and they suggest that stimulation of wound healing may be a partial explanation of the superiority of sulphathiazole in local staphylococcus infections

TREATMENT OF SEPTIC FOCI WITH WARM SATURATED SULPHONAMIDE SOLUTIONS

Green (1940) pointed out that bacteria which had been exposed to sulphanilamide were much more sensitive to the lethal action of heat Sulphanilamide was completely inactive at 0° C and there was a progressive increase in its bactericidal action as the temperature rose In the range 37°–40° C this increase in activity, using the same concentrations of sulphanilamide, was very striking It was indicated that this fact might have a clinical application Theoretically the application of a warm saturated solution of sulphonamide should greatly increase its effectiveness, mainly by increasing the local temperature but partly by increasing the concentration of the drug

The idea was tested by treating septic wounds of the fingers and hands in baths of sulphonamide solution The patient immersed the whole hand in a saturated aqueous solution (cir 1/90) of sulphanilamide sufficient to completely cover the septic wound and maintained at a temperature of 110°–120° F The period of immersion was 1–2 hours and it was repeated at 4-hour intervals The total period of immersion had to be determined individually so as to prevent the skin from becoming too waterlogged; the maximum daily period was 6 hours

Four grossly septic fingers and one septic hand, all of which had been freely incised and treated by immobilisation and acriflavine dressings for periods of 5–21 days without improvement, were given sulphanilamide baths In four of the five cases so treated improvement was progressive from the start, and within 4–10 days clinical signs of sepsis had gone and further surgical treatment (amputation or sequestrectomy) was carried out successfully In one patient with a septic hand the surface infection improved rapidly but it was necessary to make further incisions after 16 days treatment, after which rapid healing occurred Obviously, when the infected focus is not freely communicating with the surface the treatment is unavailing The result in one severely infected finger of long duration, which was treated in saturated sulphathiazole baths, was the most impressive of all, for the infection resolved in 5 days and amputation was done with safety 2 days later

We have lately extended the scope of this method by treating more varied types of infected wounds by allowing a saturated aqueous solution (cir 1/900) of sulphathiazole at a temperature of 110° F to drip upon the open wound The treatment is given for a continuous period of 1½–2 hours daily at the rate of 2 drops per second from a height of not more than 4 in After the treatment loose debris and sloughs are carefully removed and the area covered with sulphathiazole powder

Only a few cases have yet been treated in this manner but our impression is that the rate of improvement is greater than with any other method we have tried In one grossly septic amputation stump (20 days duration) with a bacterial flora of *Staph aureus*, an anaerobic streptococcus and *B subtilis*, local treatment with sulphanilamide powder for 16 days had no obvious effect, 5 days further treatment with sulphathiazole powder caused a slight improvement, but when this was reinforced with the drip treatment there was a striking improvement within 3 days

This aspect of the investigation is in its preliminary stages and the full details of our treatments with various sulphonamides will be reported later It is only mentioned because we think the early results justify its trial elsewhere, and rapid assessment of its value is of some urgency

CONCLUSIONS

The number of cases does not warrant any attempt at a statistical analysis of the details The main and important observation is that all, without exception of 14 severely infected wounds showed an early and progressive response to energetic and sustained local sulphathiazole treatment In the majority of cases this was evident during the first 3 days and in no case was obvious improvement delayed more than 13 days The rapid diminution in the amount of pus discharged and the coincident appearance of healthy granulation tissue never failed to impress us and it was usually possible to foretell by the general appearance of the patient after a few days treatment that the wound infection was subsiding

It cannot be denied that the same results might have been achieved by other methods It should however be recognised that most of these cases had previously been treated by other methods, both local and general, including vigorous systemic treatment with sulphonamides The failure of oral sulphonamides to influence the local infection was very obvious in many of our cases, though it should be noted that the infecting organism was commonly *Staph aureus* and that the sulphonamide used was either sulphanilamide or sulphapyridine, neither of which are very effective against this organism

The most impressive results in this series were, as would be expected, in purely surface infections In recent cases of this kind, treated with the warm sulphathiazole drip, the results were outstandingly good Where there is deeper sepsis it is obviously of great value to clear up the surface infection, so that surgical access is made safer We were only concerned with establishing the efficacy of local treatment, but there seems little doubt that, where the primary focus is deep as in chronic osteomyelitis, the treatment should embrace all the infected areas that can be made accessible by operation, provided that the treatment can be intensive and continuous It should not replace, but only be ancillary to, the purely surgical measures necessary to ensure adequate drainage or removal of necrotic tissues

Reviewing the results as a whole, it seems that local sulphonamide is the treatment of choice for a purely local infection, provided there is efficient access Certainly, at the present time, there is no reason to consider any other local antiseptic treatment until sulphathiazole has been given an adequate trial Undoubtedly still more effective compounds will be produced, and provided they are shown experimentally to have greater antibacterial powers, and to be no more harmful than sulphathiazole to the tissues, they will no doubt be used as they become generally available But in view of the excellent results we have obtained we recommend that, in the present emergency, sulphathiazole or sulphadiazine, which appears to have very similar properties, should be the sulphonamide generally adopted for the prophylaxis or treatment of local infection Penicillin and other powerful "biological" antiseptics like gramicidin may later displace the sulphonamides, but at present their place in local treatment appears to be where sulphonamide-resistant bacterial strains have developed in the wound

Although we have concentrated on the treatment of established infection the results have an obvious bearing on prophylaxis There is no space to consider it here, except to state that it is obviously just as important to use the most potent sulphonamide available in prophylaxis as in established infections, if unnecessary investigations are to be avoided

Finally it must be stressed that the treatment in no wise displaces accepted surgical measures and of course is of no value in sepsis below an unbroken surface A lack of understanding of the principles underlying the treatment is the main reason for the clinical arguments as to the relative merits of surgical and sulphonamide treatment Obviously they are complementary, though when intelligently used local sulphonamide treatment may often make further operative treatment unnecessary, or, as in many of our cases, enable it to be carried out safely, where it had previously been a hazardous procedure dictated by life and death considerations

SUMMARY

The mode of action of the sulphonamides is discussed in relation to their local use in the treatment of established infections

Fourteen grossly infected wounds, many of which had failed to respond to other treatments, including sulphonamides by mouth, were treated by the intensive local application of sulphathiazole

The clinical infection rapidly subsided under treatment in every case, though usually the causative organism was not eliminated

Preliminary trials with the local application of warm saturated sulphathiazole solution suggest that it may prove an efficient method of treating local sepsis

In routine clinical work at the present time, no other local antiseptic treatment of infected wounds should be attempted before the sulphonamides, preferably sulphathiazole, have been given an adequate trial

The expenses of this work were defrayed by the Medical Research Council and one of us (T P) is in receipt of a whole time personal grant from this source

We are indebted to Mr Holdsworth who permitted us to treat his cases, and to Professor Wayne, both members of the team investigating the treatment of shock and war wounds in Sheffield, and to Dr Hermitte for his assistance in bacteriological and photographic work

Messrs May and Baker gave us the sulphathiazole used in the early part and Messrs Ciba that used in the latter part of the investigations, and to both our thanks are due

PHOLEDRINE IN THE PREVENTION OF OPERATIVE SHOCK

ERNEST LANDAU, M R C S, D A
ANÆSTHETIST TO ST GEORGE'S HOSPITAL AND THE BRITISH POST GRADUATE MEDICAL SCHOOL

VALENTINE LOGUE

TEMPORARY ASSISTANT SURGEON TO ST GEORGE'S HOSPITAL

HARRY KOPELMAN
M B LOND, M R C P, D A
SENIOR RESIDENT ANÆSTHETIST TO ST GEORGE'S HOSPITAL

IN many surgical operations shock of varying degree occurs, in most cases it is mild and of short duration, disappearing spontaneously as soon as the operative manipulations or the anæsthetic are completed In more severe cases, shock can be controlled with the routine anti-shock measures combined with speed in the completion of the operation There remain some cases, however, where the patient is old or anæmic, or when long extensive operation is needed, in which severe shock becomes probable rather than possible, and its control a matter of much greater anxiety It is in regard to this latter type of case that we should like to record our clinical experience with the drug pholedrine,* which though reported on favourably by Dodd and Merton (1939) and Dodd (1940, 1942) appears to have escaped the wider recognition it deserves

We have used it prophylactically to prevent the onset of shock (its use has been disappointing in fully developed shock), and in "bad risk" patients, in whom severe shock is likely to develop despite adequate treatment (blood-transfusion, plasma, &c) It is imperative to estimate the blood-pressure repeatedly A falling blood pressure is the most constant concomitant of developing shock, we have aimed at preventing it by keeping the blood-pressure within 10%–15% of the normal preoperative level, and it is only by observation of the blood-pressure every 10–15 min that this control can be exercised

The drug can be given subcutaneously, intramuscularly or—if rapid action is desired—intravenously, and in our experience it may be repeated many times without any weakening or suppression of its biological action Experimental evidence on this point is conflicting, however (Rietschel 1939, Roberts and Ginader 1938) We found no harmful action on the heart, but reports on its cardiac effect are rather variable Some workers

---

* The pholedrine used in this investigation was 'Stimatone' (Ward, Blenkinsop & Co)

(Klostermeyer and Jonsson 1937, Parade 1938, Schoenwold et al 1940, Reis 1940) have demonstrated abnormalities of the electrocardiographic rhythm and complexes, while others maintain that it improves the coronary circulation and stroke output of the heart Many of these experiments were conducted on animals, and in one case at least the anæsthetics used were chloroform and cyclopropane—the latter being especially noted for producing arrhythmias

Pholedrine seems to have a longer and more positive action than adrenaline, ephedrine and other vasopressors, and although it might be anticipated that a patient whose blood-pressure had been continuously stimulated during an operation would tend to collapse when the stimulant was removed such has not been our experience, blood-pressure readings, continued postoperatively for many hours, have been remarkably constant. We have used pholedrine with both inhalation and spinal anæsthetics With spinal anæsthesia our method of administration is as follows Pholedrine 0 5 c cm is given 10 min before the spinal injection, should there be a significant drop in blood-pressure a further 0 5 c cm is given subcutaneously, and the blood-pressure is brought back to within normal limits If the fall has been more profound the blood-pressure can be more readily restored by giving 0 25 c cm of pholedrine intravenously followed by 0 5–0 75 c cm subcutaneously

In our earlier cases we tended to give doses which were too large and the blood-pressure would rise dramatically to 20–30 mm Hg above the preoperative level, confirming the observation of Dodd (1942)

CASE-RECORDS

The following 10 cases illustrate the value of pholedrine In all of them, despite the fact that they were extremely severe operations on patients who were poor operative risks, we were impressed by the control we had over the blood-pressure and the ease with which it could be made to return to normal, even after long operations

1 —A man of 33 with gastric carcinoma He was thin with visible peristalsis and a palpable mass Condition fair Preoperative blood pressure, 115/85 mm Hg Anæsthetic spinal 'Percaine,' 1/1500, 12 c cm, 'Pentothal,' 0 6 g, nitrous oxide and oxygen Resuscitation blood transfusion during operation, 540 c cm Total pholedrine used 2 25 c cm (1 5 c cm intramuscularly, 0 75 c cm intravenously) Operation partial gastrectomy The operation took 150 min, but the blood pressure was maintained and at the conclusion was 115/90 mm Hg When pholedrine 0 25 c cm was given 90 min after the beginning of the anæsthetic the blood-pressure was raised to 150 mm Hg systolic (fig 1) Uninterrupted recovery, after 5 months was very well

2 —A man of 34 Admitted for acute obstruction by bands Operation under spinal anæsthesia (percaine), 18 in of gut found to be obstructed but viable, and after division of band the abdomen was closed Three days later onset of pain and palpable mass in left iliac fossa Rising pulse rate, vomiting, general condition poor Blood-pressure 110/80 mm Hg Anæsthetic pentothal (0 25 g) induction followed by cyclopropane Resuscitation intravenous saline Pholedrine continued after return to ward Oxygen by BLB mask on return to ward At operation 18 in of gut was found to be gangrenous owing to a mesenteric thrombosis, this was resected and anastomosis attempted between two ends of ileum As the distal part had been injured and had to be invaginated it was decided to perform an anastomosis between the proximal ileum and transverse colon The operation took 90 min Blood pressure was maintained throughout by two injections of pholedrine 0 5 c cm On return to ward there was some fall of blood pressure corrected by two further injections of pholedrine, 0 5 c cm subcutaneously Condition after 48 hr satisfactory Patient died later from peritonitis (fig 2)

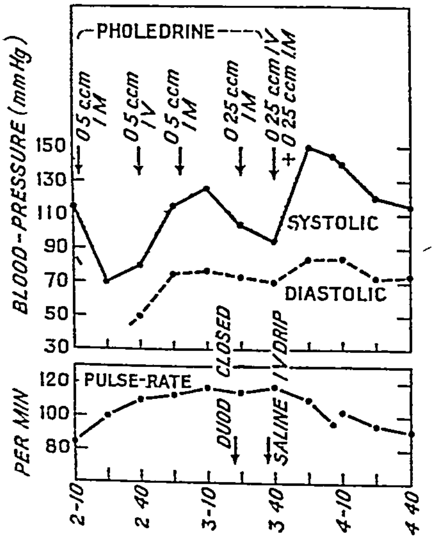

Fig 1—Aged 55 partial gastrectomy for carcinoma. Anæsthetic percaine 1/1500 12 c.cm pentothal 12 c.cm with nitrous oxide and oxygen

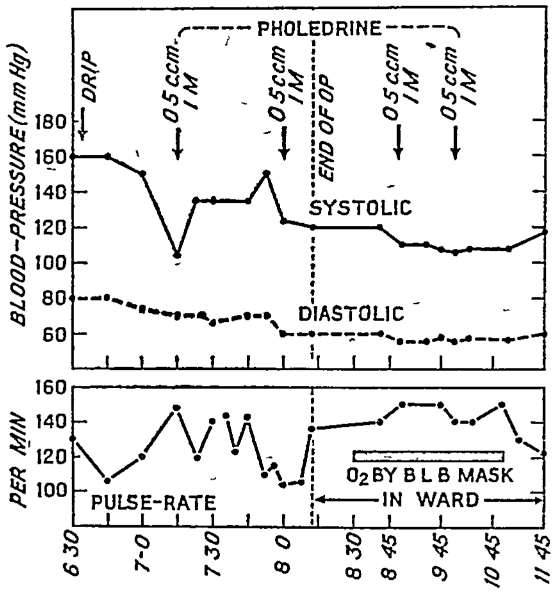

Fig 2—Aged 34, resection of small gut for mesenteric thrombosis Anæsthetic pentothal 0 25 g and cyclopropane

3 —A woman of 47 Thyroidectomy a month before for severe thyrotoxicosis when the electrocardiogram showed some slurring of the QRS complex Condition had much improved but was still retarded by an enormous ovarian cyst which was embarrassing respiration Anæsthetic bromethol, nitrous oxide, oxygen and ether Resuscitation intravenous saline, pholedrine Operation ovariectomy Blood-pressure at start 140/100 mm Hg After 60 min blood pressure fell to an unrecordable level Pholedrine 0 5 c cm restored the blood pressure to normal, and after a further slight fall it was maintained by a further injection of 0 5 c cm intramuscularly Uninterrupted recovery

4 —A woman of 72 History of coronary thrombosis 3 months before, preoperative electrocardiogram showed sinus tachycardia, T 3 inverted, left axis preponderance Blood-pressure 160/80 mm Hg Chest basal crepitations Hæmoglobin 86% Anæsthetic spinal percaine, 1/1500, 10 c cm, pentothal 0 25 g, gas and oxygen Resuscitation pholedrine Operation vaginal hysterectomy After administration of anæsthetic blood pressure fell to 100/15 mm Hg despite pholedrine 0 5 c cm. given intramuscularly 15 min before Further doses of 0 25 c cm intravenously and 0 25 c cm intramuscularly soon restored blood-pressure to 130/70 mm Hg A later injection of pholedrine 0 33 c cm intramuscularly restored blood pressure to normal Duration of operation, 80 min Postoperative electrocardiogram showed no change Uninterrupted recovery

5 —A man of 49 Condition poor, anæmic, Hb 38% Palpable mass in abdomen Previous gastro-enterostomy; diagnosed as doubtfully operable carcinoma of the stomach Given blood-transfusion preoperatively and Hb brought up to 65% Anæsthetic spinal percaine, 1/1500, 13 c cm, pentothal and cyclopropane Operation partial gastrectomy Duration 180 min Blood pressure maintained by small injections of pholedrine and patient was returned to ward in fairly good condition Uninterrupted recovery

6 —A man of 57 Thrombocytopenic purpura Developed profuse and widespread hæmorrhages and had to be given, in all, 4 l of blood and 420 c cm of concentrated red cells before bleeding ceased and progress was made Three months later Hb 70% Splenectomy Duration 80 min Anæs-

thetic spinal percaine, 1/1500, 12 c cm pentothal (continuous) 0 5 g Resuscitation pholedrine 0 25 c cm intravenously, 1 25 c cm intramuscularly Blood pressure 110/80 mm Hg at start of operation, fell after ½ hr to 85/40 mm Hg Pholedrine 0 25 c cm intravenously and then repeated doses of 0 25 c cm intravenously and 0 75 c cm intramuscularly, with restoration and maintenance of blood pressure which at conclusion of operation was back to normal Uninterrupted recovery

7 —A man of 63 Developed suppurative cholecystitis while recovering from amputation of leg through thigh for thrombophlebitis obliterans Previous lumbar sympathectomy for same condition Blood pressure 150/80 mm Hg Fat, poor myocardium Râles at both bases Anæsthetic spinal percaine, 1/1500, 13 c cm , cyclopropane and oxygen Resuscitation pholedrine Operation cholecystotomy Duration 45 min At start there was a sudden fall of blood-pressure which was quickly restored by pholedrine 0 5 c cm intravenously and was maintained by 2 5 c cm intramuscularly in divided doses After 30 min operating a further fall to 100/65 mm Hg was restored to normal by 0 5 c cm intravenously Uninterrupted recovery

8 —A woman of 52, air-raid casualty Multiple injuries, including one perforating peritoneum On admission, blood pressure 115/78 mm Hg, pulse-rate 70 Given 400 c cm of plasma, 2½ hr later blood pressure 140/78 mm Hg, pulse rate 72 Taken to theatre wounds, including abdominal wound, explored and treated Duration 135 min Anæsthetic pentothal, 1 5 g (continuous), nitrous oxide and oxygen Resuscitation in theatre further 200 c cm serum intravenously, pholedrine Blood pressure at conclusion of operation 155/80 mm Hg Uninterrupted recovery

9 —A woman of 51 Symptoms of obstruction and irreducible femoral hernia for 12 hr Pale, dehydrated, vomiting Operation femoral sac incised but as obstruction was released bloodstained fluid flowed from general abdominal cavity Laparotomy showed strangulated dead gut over large caseous gland Resection of gut Duration 195 min Anæsthetic spinal percaine, 1/200, 2 c cm , cyclopropane Resuscitation saline, pholedrine Uninterrupted recovery

10 —A man of 59 Perforated duodenal ulcer for third time Condition fair but dehydrated Operation suture of perforation and gastro enterostomy Duration 120 min Condition maintained throughout Anæsthetic hexobarbitone 0 5 g , cyclopropane and oxygen Resuscitation intravenous saline, pholedrine Uninterrupted recovery

DISCUSSION

We have used pholedrine in cases in which owing to the state of the patient or the extent of the operation shock has been likely to develop We have hoped to avoid irreversible or profound shock by keeping the blood-pressure as constant as possible and restoring it to normal as soon as possible For this we have found pholedrine of great value Once " irreversible " shock has developed pholedrine is of no value We have not encountered this in our operation cases, but have seen it in severely shocked air-raid casualties and have found little or no response to pholedrine, unfortunately the records of these cases were either lost or not kept owing to the blitz Pholedrine does not replace adequate preparation of the patient preoperatively by blood-transfusion, saline infusion or other necessary measures Similarly, if pholedrine is to have its full effect during operation the blood-volume must be maintained by transfusions of blood or plasma, or by intravenous infusions Under these conditions we have not found it necessary to use any other cardiac or respiratory stimulant

We wish to thank our colleagues at St George's Hospital for their cooperation during this investigation

THREE CASES OF LOCKED TWINS

STANLEY W WRIGHT, M B LOND, M R C O G
ASSISTANT MEDICAL OFFICER, WEST MIDDLESEX COUNTY HOSPITAL, ISLEWORTH

THE locking of twins is rare, though the number of cases published in the past few years seem to indicate that it is getting less so This might be expected if it is true that ordinary twin pregnancy is becoming more common The only statistics which I have been able to discover are those of Von Braun (quoted by Eden and Holland 1937), who from Viennese figures estimated that it occurred once in 90,000 labours This gives a rate of 1 in every 1000 twin labours Many obstetricians of wide experience have never encountered the condition, and I must account myself fortunate in having treated three cases in the past six years

There are five ways in which locking or collision may happen The fœtuses are usually small or the pelvis very large

1 The fœtuses both presenting by the vertex, their heads enter the pelvis side by side and become arrested If, however, the heads are very small, spontaneous delivery may ensue The treatment is to push up the heads above the pelvic brim, if possible, and deliver the babies separately, as a rule by forceps extraction Firm impaction may necessitate craniotomy of one or both heads before delivery can be effected

A case of this type was reported by Commandeur and Eparvier (1923) They were able to reproduce the condition found, since the fœtuses though stillborn were not mutilated, and they published a photograph showing the manner in which the head of the second twin fitted the neck and shoulder of the first Phillips (1926) reported a similar case, where the impaction of the head was such that disengagement was impossible He perforated the cranium of the first fœtus, severed the neck and removed the head before he was able to push up the trunk and deliver the second child Both fœtuses were macerated The mother made a good recovery Dawson (1936) also reported such a case and since the diagnosis was made before the os was fully dilated and both babies were alive he performed a lower segment cæsarean section, saving both children The puerperium was uneventful

2 The first child presents by the breech, the second by the vertex the heads either become impacted in a manner similar to that of the previous type or become locked by the chins Rarely, spontaneous delivery may take place

McClintock (1876) cited two cases in which nature succeeded in overcoming the obstacle In rare instances, the chins may be disengaged by internal manipulation and delivery completed Moore (1933) was able to do this by a process of rotation and traction, and delivered the second child alive Here, the delay arose when the feet of the first child presented at the vulva in a footling presentation—i e , the fœtus was still high in the pelvis—and this probably accounted for the ease with which delivery was effected More often the heads are firmly fixed in the pelvic brim or cavity and cannot be disimpacted There are then two courses open Since the first child is known to be dead, it may be decapitated, the trunk removed and the head pushed up, when the second fœtus can be delivered by forceps and the first head ultimately removed Or the head of the first child may be perforated through the mouth and extracted, this method being suitable only in cases in which collision and not locking has occurred McClintock (1876) mentions one case in which decapitation was performed " with a bass string wrapped round with wire of a pianoforte " I learn that, adopting a similar principle, even the unmusical may perform decapitation with a wire such as is used in a Gigli saw passed around the neck by means of a Blond-Heidler needle Severance of the neck with embryotomy scissors can be a tiring and difficult process, as I discovered, with the hand confined within a fully occupied pelvic cavity The decapitation hook is not designed for, and is valueless in, this type of case

3 The breech of the second child, with the legs flexed, enters the brim at the same time as the thorax of the first child, also presenting by the breech, preventing further progress of the first child, whose head remains abo[illegible] brim

This happened in the third of my cases, but I have not seen it described previously. I would have expected this type of locking to be relatively common, and no doubt such cases have been recorded which I have overlooked in my necessarily limited survey of published work. Further progress in such a case, if it could take place, might result in a double footling presentation as described below (type 5). Spontaneous delivery would be very unlikely, although treatment proved relatively simple.

4. The first child presenting by the breech or the feet may become locked by the chin on the body of the second child, lying transversely. Natural delivery is impossible. Decapitation of the first twin should be performed, and an effort made to save the second by version and extraction.

Ackermann (1920) reported a case in which the lower fœtus presented transversely by the shoulder, while the head of the second was lying in the pelvis, the arm of the transverse twin preventing descent of the second head. By pushing up the arm above the brim he was able to extract the second child with forceps; afterwards an internal version was performed on the first, around which the cord was looped in a complicated fashion. Both children survived.

5. Both fœtuses presenting as footlings may enter the pelvis together.

Again McClintock (1876) is my source of information, and I can do no better than quote his own words:

“ Of the other variety of bifœtal presentation Amand relates a case where he found three feet presenting. By careful examination he ascertained the two belonging to the same fœtus and brought them down. Dr. F. H. Ramsbotham was once called to a case where a leg of each child was beyond the vulva. ‘Although they were right and left,’ he remarks, ‘I immediately detected by the direction of the toes that they belonged to different bodies; by gently pushing up one, and careful traction at the other leg, I extracted each breech from the brim of the pelvis and both children were born living.’ ”

Few cases of this type can end as happily as this last—embryotomy is usually the fate of both children. Smellie himself, with his vast experience, makes no reference to this complication of twin labour, and it must therefore be assumed that he never saw such a case.

CASE 1

A primigravida, aged 21, was admitted to hospital on Feb. 19, 1936, in the 38th week of pregnancy according to her dates. Though dirty and self neglected, she appeared healthy; she was a heavily built, unintelligent girl who had had no ante-natal care. Apart from a moderate rise in blood pressure she had no toxæmic manifestations. External measurements were large and the uterus was the size of a full time pregnancy. A presenting part was in the pelvis, but the fœtal parts were indefinite and difficult to determine owing to tenseness of the uterus. At this time only one fœtal heart was made out, to the left of the umbilicus. On vaginal examination, the soft parts were normal. The pelvis was very large; the promontory was not reached and the outlet was normal. The presenting part was difficult to determine because she resisted examination, but was thought to be a small breech. An X ray revealed twin pregnancy, the first fœtus presenting by the breech with legs flexed and back to the left, the second—a smaller fœtus—presenting by the vertex with back to the right.

Labour came on at 1 A.M. on Feb. 20. At this time (the X ray having no doubt assisted localisation) two fœtal hearts were audible: one to the left and just below the umbilicus, the other to the right above the navel. Labour proceeded normally until 8.50 A.M., when the membranes of the first fœtus presenting at the vulva, were ruptured artificially and a foot presented; 30 min. later the buttocks were born, the sacrum to the left and anterior. Labour continued naturally until the umbilicus was born, when the cord was found to have stopped pulsating. The arms, which were flexed, were hooked out of the vagina, and traction applied to the legs, without causing any advance of the fœtus. At 9.45 A.M., with the patient anæsthetised, I passed a hand into the vagina, which was unusually capacious, and into the uterus posteriorly. I found that the chin of the first fœtus, pointing to the right, had become locked with that of the second, lying towards the left. The two heads were firmly wedged in the lower uterine segment, and could be felt lying together on abdominal palpation. The second fœtal heart was still audible. The neck of the first twin felt elongated, no doubt as a result of efforts at extraction. I was unable to push up the head of the first fœtus, or otherwise disimpact the chins, and therefore decided to decapitate the first fœtus in an endeavour to save the second. The cord was severed between forceps. Since the vagina, though roomy, was uncomfortably tight for the hand in its upper part, the first fœtus was rapidly eviscerated through the abdomen, the thoracic contents being drawn out through the diaphragm. I then passed my left hand along the back of the fœtus, between it and the anterior vaginal wall, and my index and middle fingers over the shoulders, as in shoulder traction. A stout pair of curved scissors, similar to those used for morcellement, was then passed upwards between the hand and fœtal back, and, with my fingers protecting the maternal tissues from the blades, I severed the neck in the lower cervical region. The trunk being thus removed, the head was readily pushed up past the second fœtus after a long vulsellum had been attached to the cut tissues of the neck. The head of the second fœtus was then brought manually into the pelvic cavity, light forceps applied, and the child delivered in the left occipito anterior position, complete in its membranes. The sac was very lax and contained almost no liquor, so that I had previously thought them to be ruptured. The child was very small and in a profound state of shock; it did not survive its birth, for respiration was never established. A second vulsellum was attached to the neck of the first head, which was then easily delivered by traction. The placenta, of the fused binovular variety, was delivered 8 min. later. The uterus contracted well without abnormal loss. There were no soft tissue lacerations.

The operation occupied 1 hr. 10 min. The patient's condition after these tedious manipulations was excellent, her blood-pressure being maintained at 136/80 mm. Hg. Both fœtuses were female. The first, without the viscera, weighed 4 lb. 10 oz., and the second 2 lb. 13 oz. No other measurements were recorded. The puerperium was normal in every way. The patient left hospital on the 12th day after delivery, at which time involution was proceeding normally, although the uterus was still somewhat bulky. She did not return for postnatal examination.

CASE 2

A recently widowed primigravida, aged 34, auburn haired, highly strung and of good physique, first attended my ante natal clinic on March 2, 1937, when 25 weeks pregnant. I found no physical abnormality, and the blood pressure and urine were normal; but the uterus was the size of a 28 weeks pregnancy. She attended the clinic until April 12, when she began to complain of headaches, vomiting, and swelling of the legs. I admitted her, since her blood pressure was 150/80 mm. Hg, and she had gross œdema of the legs and feet, though the urine was normal. By her dates she was 30 weeks pregnant, but the uterus was the size of a 34 weeks gestation. It was tense, and the fœtal parts indefinite. What I took to be a head was above the brim, but to the left of the umbilicus was another ballottable part which felt like a second head. A fœtal heart was heard to the right of the umbilicus, and another at the fundus, though there was little difference in the rates. X rays confirmed the presence of twins. One fœtus lay in the right oblique position with its head just above the brim; the other at a much higher level, with its head to the left of the umbilicus and the breech at the right fundus, the back occupying the fundus to the left.

The patient improved rapidly and was able to leave hospital 6 days later, but in a week was readmitted with similar toxæmic symptoms. The blood pressure was now 180/100 mm. Hg and there was albumin in the urine. Despite drastic treatment she improved only up to a point; the albumin never quite disappeared from the urine, and the blood pressure was never below 130/80 mm. Hg. Urine sterile; no casts. Blood urea normal.

On May 21, 26 days after admission, I decided to induce labour. The uterus was the size of a full-time pregnancy, and the pelvis roomy. I found a breech entering the pelvis, head at left fundus, back to the left; the other child was a vertex with head in the right iliac fossa and back to the right. Both fœtal hearts were normal. There had thus been a considerable readjustment of the fœtal positions since the X ray had been taken. Three doses of quinine sulphate, gr. 5, were given at 2 hourly intervals, the last dose at 12 noon. Labour started with vague pains at 12.30 P.M., becomin stronger by 1 P M when I saw the patient and was satisfied with her condition For the next 12 hours I was absent from hospital, and this part of the story was reported to me by the nursing staff and by a colleague who was called in At 1 30 P M the patient vomited, but seemed to be progressing normally She was transferred to the labour ward at 3 P.M , blood pressure 210/130 mm Hg Shortly afterwards she collapsed , she was pale and cold, with pulse rate 56 per min Both fœtal hearts were slow The labour pains almost disappeared At 7 P M the patient's general condition was the same The fœtal hearts could no longer be heard Pains weak and irregular On rectal examination the breech was in the upper pelvic strait, and the os 2–3 fingers dilated The membranes ruptured shortly afterwards, and at midnight a foot appeared at the vulva At 12 30 A M on May 22 I saw her again She was in a desperate condition and looked profoundly shocked She was pale, with a cold, moist skin and clammy extremities despite numerous hot bottles Pulse thready, 154 , blood-pressure 194/148 mm Hg I concluded she was suffering from some unusual toxæmic manifestation, but have since thought this must have been a case of quinine idiosyncrasy, as a colleague suggested at the time Treating her for toxæmia, I removed 15 oz of blood by venesection and replaced it by 150 c cm of 50% glucose saline solution and 10 c cm of 10% calcium lævulinate , after this I gave morphia, gr $\frac{1}{6}$ She appeared a little better , her pulse rate fell to 136, and her blood pressure to 160/110 mm Hg At 3 A M she vomited 10 oz bloodstained fluid Morphia, gr $\frac{1}{6}$ was repeated, and she slept for short periods At 5 30 A M she again vomited bloody fluid Blood pressure had fallen to 144/124 mm Hg Occasional pains, with slow advance of the fœtus , general condition stationary At 8 A M the breech was born to the umbilicus An hour later her general condition was deteriorating , her blood-pressure was only 110/90 mm Hg and pulse rate 144 Morphia, gr $\frac{1}{4}$, and a subcutaneous saline were given An hour later there was no improvement, and I gave her 30 oz of gum saline with 10% glucose, with improvement which was maintained Labour pains had disappeared At noon the pains recurred and were now much stronger The body was born as far as the costal margins, but then progress became arrested despite increasingly strong pains On abdominal examination I found that the heads had become locked together above the brim, the head of the second fœtus lying lower than that of the first whose body was already partly born By abdominal manipulation I could not disengage the second head from above the pelvic brim into the right iliac fossa, and therefore decided, with some misgivings on account of her poor condition, to examine her under anæsthesia

Under gas, oxygen and ether I passed my hand into the vagina posteriorly after bringing down the flexed arms, and upwards into the lower uterine segment I found the head of the second fœtus lying transversely and extended with its face towards and wedged in between the shoulder and head of the first child The neck of the first child and the occipito frontal diameter of the second child occupied the transverse diameter of the brim By pushing up the body of the first fœtus with my outside hand I was able to rotate the second head to bring the occiput to the front, which had the desired effect of disengaging the face from the root of the neck of the first child After pushing the second head into the uterine cavity to the right, I readily extracted the head of the first child The second bag of membranes was then ruptured artificially, releasing only a small amount of liquor, and the fœtus extracted with forceps The placenta, of the fused binovular variety, was expressed 20 min later Ergometrine and 'Pitocin' (PDCo) were given and the loss was very slight

Both infants were born dead The first was a male, weighing 4 lb 1½ oz , length 18 in , the second a female, weighing 4 lb 11 oz , length 19¾ in

The patient's condition at the close of the operation—which only lasted 15 min —was rather poor , blood-pressure 134/76 mm Hg, pulse rate 120 Continuous proctocylsis with 5% glucose solution in saline was instituted The same evening I observed ecchymoses of the skin of the abdominal wall, at the sites of injection of the various drugs, and on the arm where the tourniquet had been applied before the intravenous injections Since the onset of the acute illness, 24 hours before, the urine had contained much blood Lederle's viper venom, 0 4 c cm , was given intramuscularly and repeated later , there was no subsequent hæmorrhage The patient, though she appeared to have cystitis, improved rapidly until the 9th day of the puerperium, when her lochia became offensive and gradually more profuse, though her general condition was good and there was no pyrexia She was examined vaginally a day or so later, and a vesicovaginal fistula about ¼ in in diameter, surrounded by necrotic tissue, was found about 1½ in within the introitus I could not account for its appearance in an area subjected to no trauma whatever during labour The urine became normal with the administration of acid sodium phosphate, gr 30 t d s , and I closed the fistula under spinal anæsthesia about four weeks after it was discovered When seen a month later she was in good health and was passing urine normally The fistula was completely healed, and both urine and blood pressure were normal

CASE 3

A primigravida, aged 24, was admitted in labour on Feb 4, 1941. She was at term according to her dates, and said she had attended an antenatal clinic during the latter months of pregnancy She had booked a midwife and was to have had her baby at home Her last attendance at the clinic was 3 days before the onset of labour Labour began with pains of a minor character at 1 A M on Feb 1, but she did not call in her nurse until 6 P M two days later The midwife examined her vaginally , there was no dilatation and the presenting part was high A mild sedative was given At 1 15 A M on Feb 4 the os was fully dilated, and the midwife thought she felt " a hand in front of a vertex " She therefore called in a doctor, who examined the patient at 4 15 A M , finding a foot presenting He also diagnosed twin pregnancy, and sent the patient into hospital

On admission, at 5 40 A M , she was distressed The pulse rate was 130, the tongue furred and the mouth dry There was considerable œdema of the legs and the face was puffy Pains were strong and almost continuous A foot was protruding from the vulva, but it did not descend with the pains The uterus reached to within 2 in of the ensiform cartilage One head was palpable above the pubes in the midline, the other at the fundus to the left Only one fœtal heart was audible, to the left of the umbilicus I thought some kind of locking might have occurred At 6 20 A M she was given 0 8 c cm of 'Heavy Percaine' intrathecally A foot was protruding from the vulva, the legs and body of the first child occupied most of the pelvic cavity, with the back facing backwards , the cord was pulsating The os was fully dilated The pelvic brim was occupied anteriorly by the neck of the first child, while behind it the flexed legs and buttocks of the second child had descended just below the level of the brim, the legs being in front, occupying the nape of the neck of the first fœtus, and thus preventing the descent of the first head into the pelvic cavity The membranes of the second fœtal sac were unruptured, but the amount of liquor was very small The lower pole of the second fœtus was easily pushed up above the brim, so disengaging the legs from the nape of the first child By traction on the presenting leg the head of the first baby was then brought into the pelvis and a living child delivered with moderate ease at 7 A M At 7 10 A M 5 units of pitocin were given, and the membranes of the second fœtus were ruptured artificially with escape of a small quantity of liquor The breech engaged at once, and a living child was spontaneously delivered half an hour later The placenta separated almost at once, and could be seen protruding from the vagina It was therefore expressed, complete with membranes, five minutes later Loss was scanty but ergometrine, 0 5 mg , was given intramuscularly The placenta was of the uniovular variety, with separate amniotic sacs

Both children were males and apparently healthy The first weighed 3 lb 15 oz , the second 4 lb 5 oz The first died on the 4th day, after a convulsion , permission for autopsy was not obtained The second child was reared satisfactorily The puerperium was uneventful

DISCUSSION

The causes of twin locking can only be conjectured, but there are some conditions which undoubtedly predispose to it Except in the very unusual type in which a limb of one fœtus enters the pelvic cavity and blocks the descent of the other, the pelvis must be large and the presenting parts small A normal amount of liquor in each fœtal sac will probably prevent locking, and I believe we can go further and say that a deficiency of liquor in the second fœtal sac favours the accident Dawson (1936) suggested that this might be so, having observed oligohydramnios in his case , Phillips (1926) made the same observation, and there was oligohydram nios of the second fœtal sac in all of my cases. Unfortunately the amount of liquor in the second fœtal sac is not specifically mentioned in most of the case-reports I have studied. Premature rupture of the second membranes might, I presume, predispose to locking.

It might be expected that mono-amniotic twin pregnancy would conduce to locking or collision of the fœtuses. Quigley (1935) denies that locking is commoner in such cases, but the total number of mono-amniotic twin pregnancies so far reported is little over 100. When one studies the disposal of the fœtus in cases of multiple pregnancy—the dovetailing together, as it were, of the babies in order to economise space—it seems remarkable that locking does not take place more often.

SUMMARY

Five common types of twin locking are described, and 3 cases reported in detail.

Predisposing factors are a large pelvis and relatively small fœtal parts, and oligohydramnios of the second fœtal sac may be important.

PANCREATITIS AND DIABETES

RODNEY SMITH, M S LOND, F R C S
LATELY SURGICAL REGISTRAR AT THE MIDDLESEX HOSPITAL

THE normal function of any organ is liable to be affected adversely by gross destructive lesions. It is curious, therefore, that while there is little argument about the importance of the pancreas in the pathology of diabetes mellitus, most surgical textbooks, in discussing acute pancreatitis, pay little attention to diabetes as a possible complication. It is true that the part played by the pancreas is even now not fully understood, but there is no doubt that secretion of insulin is a property of the islets of Langerhans; since these are scattered throughout the pancreas, it seems reasonable to assume that if a large part of the pancreas is completely disorganised by disease the destruction of islet tissue should result in a diminution in the secretion of insulin. A recent case in which acute pancreatitis was associated with postoperative diabetic coma, with fatal results, prompted a study of the published cases to ascertain whether diabetes is an excessively rare complication of pancreatitis, or whether the possibility should be considered in every case and steps taken accordingly.

CASE-REPORT

A woman of 53 was admitted to the Middlesex Hospital with the following history, the salient points of which had to be obtained from relatives, owing to her poor condition. Until a week before she had been well. There were no significant illnesses in her history, except possibly one attack of jaundice 20 years ago, lasting "a week or so," and nothing to suggest previous diabetes mellitus. A week before admission she had been seized with severe abdominal pain mainly epigastric but felt to a lesser degree over the whole abdomen. She stayed in bed, feeling very ill and in great pain, and unable to take anything but fluids by mouth; a doctor was not consulted until 5 days later, the pain now being worse and accompanied by abdominal distension and vomiting. She was admitted to hospital 2 days later with a diagnosis of peritonitis of unknown origin. Just before admission she had been given an injection of morphia, gr ½.

She was very drowsy, with pin point pupils, but able to coöperate to a certain extent. Abdominal pain was still severe. There was no backache. Temperature was 103·4° F and pulse rate 116 per min. She appeared very ill and dehydration was well marked. There was profuse, effortless vomiting of dark brown intestinal contents. The abdomen was grossly distended, with hyper resonance, a little free fluid in the flanks and no diminution of liver dullness. There was generalised tenderness, most obvious in the upper half of the abdomen. On auscultation, peristaltic sounds were completely absent. Examination of the urine, removed by catheterisation, revealed no abnormality. The odour of the breath was such that had acetone been present it is doubtful if it would have been detected.

The patient was so obviously in extremis that it was impossible to make a certain diagnosis, but in view of the unmistakable ileus and the fact that the pain was mainly in the upper abdomen, the most likely diagnosis was thought to be diffuse peritonitis, probably caused by perforation of a peptic ulcer or the gall-bladder. Intravenous drip saline was started. The stomach was emptied of its foul intestinal contents by aspiration with a large stomach-tube, after which continuous suction-drainage was instituted with a Ryle's tube and a modified Wangensteen apparatus. The abdomen was opened by a midline epigastric incision, under local 'Percaine' field block and light cyclopropane and oxygen anæsthesia. A little free peritoneal fluid found, but no peritonitis, though both large and small gut were greatly dilated. There was no fat necrosis. The cause of the ileus was not long sought, for on palpating the region of the pancreas, a mass about the size of a tennis ball was felt, apparently occupying the whole of this organ. When the mass was approached through the gastrocolic omentum, it was found to be tensely cystic, and a finger was easily inserted into a large abscess cavity from which was evacuated a considerable quantity of foul, stinking pus and several sequestra of necrotic pancreatic tissue. Culture gave a pure growth of *Bacterium coli*. The abscess was drained with a piece of corrugated rubber and 15 g. of powdered sulphanilamide was implanted locally. The patient did not regain consciousness from the anæsthetic, but passed straight into diabetic coma; 15 hours after operation acetone could be detected in the breath, and the blood sugar was 420 mg. per 100 c.cm., blood urea 110 mg. per 100 c.cm. Measures to combat this unexpected catastrophe were at once instituted, but though temporary improvement at one point gave grounds for hope, and the blood sugar was brought down to 111 mg. per 100 c.cm., she died 3 days after operation. Autopsy revealed that almost the entire pancreas had been destroyed; in addition she had portal pyæmia with multiple abscesses in the liver, and bilateral bronchopneumonia.

DISCUSSION

Though so little attention has been paid to diabetes as a complication of acute pancreatis, published cases show that disturbances of carbohydrate metabolism are common in cases of pancreatitis. In 1862 Harley described a case in which there was glycosuria, and Atkinson described a similar case in 1895. Fitz (1889), in his original papers on acute pancreatitis, does not mention diabetes as a complication. Korte (1911) reported 44 cases of acute pancreatitis, in 6 of which there was glycosuria. The evidence suggests that while glycosuria with acute pancreatitis is by no means rare, it is present in only a relatively small percentage of cases. Shumacker (1940) places this figure at 11%. If glycosuria is not common, most workers agree that hyperglycæmia is. Douglas (1933) placed little reliance on estimation of the blood-sugar as an aid to diagnosis, but Cole (1938) believes it can help; Brocq and Varangot (1937) collected 72 cases in which the blood-sugar had been estimated and found that in 15 of these it was below 150 mg. per 100 c.cm., in 23 it was between 150 and 200 mg., and in 34 over 200 mg.

In most of these cases of glycosuria and hyperglycæmia the disturbance of carbohydrate metabolism was only temporary. There are, however, a number of reported cases in which true diabetes was caused by acute pancreatitis. Schmieden and Sebening (1937) analysed 1278 cases of acute pancreatitis, of which 624 survived and 18 developed diabetes. Shumacker (1940), in his exhaustive survey, collected 62 cases of diabetes caused by acute pancreatitis published up to that date; 25 developed diabetes during the acute illness, and of these 6 died in diabetic coma soon after operation, 13 died of some other cause during the acute illness, 6 survived the acute illness, but 2 of them died of diabetic coma later. 37 cases developed diabetes, 4 soon after recovery from the acute illness, and 33 more than a year afterwards. According to Shumacker, there are also about 19 cases on record of acute pancreatitis occurring in patients previously known to be diabetics, all fatal but one. A smaller number of cases have been reported of diabetes associated with cysts and pseudo-cysts of the pancreas (Donati 1932, Simsch 1932, Lebon and Loubeyre 1932, and others)

Disturbances of carbohydrate metabolism may also occur, though far less commonly, with chronic pancreatitis Cases of this kind associated with glycosuria have been described by Mallet-Guy and his colleagues (1936) and by Plauchu and Loras (1935) True diabetes is even less commonly associated with chronic pancreatitis, Mosenthal (1937) associates chronic pancreatitis with the slowly progressive essential diabetes of Naunyn, while Sweeney (1931) recorded a case in which chronic pancreatitis with obstruction of the common bile-duct and main pancreatic duct led to obstructive jaundice and diabetes, cholecystojejunostomy cured both the jaundice and the diabetes Less straightforward are the cases of Iberti (1940) and Ehrstrohm (1932), in both of which chronic pancreatitis led to functional hyperinsulinism

Some conclusions may be drawn about the incidence and importance of diabetes in inflammatory conditions of the pancreas In chronic pancreatitis true diabetes is rare It will be remembered that in cases of spontaneous hyperinsulinism not associated with an islet-cell tumour, surgical treatment to be successful involves the removal of about six-sevenths of the pancreas It seems probable that chronic pancreatitis will not cause diabetes unless a similar proportion of islet tissue has been destroyed or rendered inactive by inflammatory changes, which of course happens rarely The uncommon association of chronic pancreatitis with hyperinsulinism may possibly be explained by analogy with the known physiology of another gland having an internal and external secretion—the testis Ligation of the vas and obstruction of the external secretion causes an increase in the internal secretion, and in the pancreas it is possible that chronic pancreatitis, particularly if confined to the region of the head, may cause obstruction to the external secretion while destroying little or no islet tissue An increase in the internal secretion may result

In acute pancreatitis, extensive destruction of the pancreas is far commoner, and the number of cases associated with diabetes is correspondingly greater Even if true diabetes is not present, glycosuria occurs in about 11% of cases (Shumacker) and hyperglycæmia in a much higher percentage Acute pancreatitis in the previously diabetic is almost invariably fatal, only one case with recovery being recorded Should diabetes appear for the first time as a complication of acute pancreatitis, chances of recovery are small, in Shumacker's series only 6 surviving out of 25, and 2 of these dying soon after of diabetic coma It is probable that the formidable combination of a major abdominal catastrophe and diabetes is made even more lethal than need be by failure to consider diabetes as a possible complication, and consequent failure to recognise the condition and institute treatment at the earliest possible moment

It is clear that diabetes mellitus is, though uncommon, by no means a negligible complication of acute pancreatitis, and that minor temporary disturbances of carbohydrate metabolism, so far from being uncommon, are the rule Acute pancreatitis is itself not common, yet 4 cases were treated on one surgical firm at the Middlesex Hospital within two months Greater importance should be attached to estimations of blood-sugar as an aid to diagnosis in obscure cases in which pancreatitis is suspected, and in cases of proved acute pancreatitis routine blood-sugar estimations are advisable When one of these unusual cases does come under treatment, such measures might make it possible for early treatment to save a life that would otherwise be lost

I wish to thank Mr R Vaughan Hudson for his help and for permission to report this case, and Dr R W Scarff, of the Bland Sutton Institute of Pathology, and Prof E C Dodds, of the Courtauld Institute of Biochemistry, for permission to refer to pathological and biochemical data

MASS RADIOGRAPHY

VOLUNTARY SCHEME IN A FACTORY

G B STANFORD, MRCS, ARPS

With supplementary notes on technical organisation by

K C CLARK, FSR

THE application of mass radiography to industry is in its infancy in this country The technical side is well explored and satisfactory records are obtainable, but the problem of the organisation of a scheme in a factory, although of equal importance, has not been much discussed In this paper will be presented a brief report on the results obtained from 600 people employed by a radio company, with special reference to the way in which the workers received the scheme

THE ROUTINE

At the start a memo describing tuberculosis, its effect on production and the justification for using mass radiography as a means of early diagnosis was given to the management Then, through the help of Sir Wilson Jameson, the prompt treatment of any early cases which might be detected was assured The people to be X rayed were drawn from the scattered factories of a large company in North East London, and they all had to travel to the X-ray apparatus The scheme was made possible by the kindness of Miss K C Clark of Messrs Ilford, who put the equipment and facilities of her department at my disposal for as many people as I cared to bring After a few teething troubles, the following organisation was adopted

Names were collected by the factory nurses and were placed on a waiting-list, Note A being sent to every applicant The X ray was taken every Thursday as soon after 5 30 as possible, so Notes B and C were sent out each Friday morning—that is, just one week ahead At 5 30 on the Thursday they assembled as directed and were escorted down by bus to the premises of Messrs Ilford at BMA House It should be noted that the workers came in their own spare time and at their own expense They were encouraged to bring, and in many cases did bring, their mothers, brothers, sisters, sweethearts and children, but the scheme did not include friends, the idea being that immediate family contacts should be incorporated

NOTE A —WELFARE DEPARTMENT

Your application for X ray has been received and I have placed your name on the waiting list

At present X rays are done every Thursday evening, and you will be given a week's notice of your appointment

FACTORY MEDICAL OFFICER

NOTE B —WELFARE DEPARTMENT

Arrangements have been made for you to be X rayed on Thursday Sister Smith will meet you in the entry hall at 5 30 in the afternoon to take you to Tavistock Square

Please bring this notice to the attention of your foreman or departmental head

If for any reason you are unable to be present on this day, please let me know immediately so that I may make arrangements for someone else to take your place and give you another appointment

FACTORY MEDICAL OFFICER

On arrival at the premises the workers filled in a card (Note D) which, besides providing the means of identification in the apparatus, was used as a record, the X ray report being written on the back later The men and women were then separated and the men taken to the X ray room, where they stripped to the waist and were quickly radiographed While this was being done the women undressed to the waist and put on pyjama jackets The men were then sent to dress in another room and the women brought into the X ray room

This procedure worked quite smoothly, and 30 people, even under the relatively uncontrolled conditions, were done in the space of ¾ hour At the beginning height, weight and chest expansion were also taken, but this was found to slow up procedure too much and was discontinued With suitably designed changing accommodation and restriction to one sex per night, the rate of work could have been materially increased, but speed was not attempted

NOTE C—FACTORY MEDICAL OFFICER

I shall }
I shall not } be present on Thursday,
for my X-ray appointment
Signature

The miniature radiograms were interpreted by experienced radiologists, and I am indebted to Dr H Courtney-Gage and Dr K Poulsson for helping me in this way As soon as the results were known they were entered on the backs of the cards which the workers had filled in, and were sent back to me by post Form E was sent out in a sealed envelope immediately, so that usually each person knew the result within a week of the X ray being taken A large gap was left between the text and the signature so that special comments could be inserted—usually to the effect that there was evidence of some trouble having occurred at some time which was of no significance to the worker's present health

NOTE E—WELFARE DEPT

With reference to your X-ray taken on , I am pleased to be able to tell you that the Indirect Radiograph shows no evidence of any abnormality in your chest

FACTORY M O

Height in shoes, ft in
Weight, partially dressed, lbs

By this method a point was made of informing the worker of any abnormality however slight so that, if it were rediscovered later on, the miniature radiographic technique adopted could not be blamed for having missed it Any miniature radiogram suggesting abnormality was retaken on full-sized film before a diagnosis was attempted and, so that people should not think that their being recalled for this purpose necessarily meant that they had tuberculosis, I made a point of recalling at least two people from every weekly group

If the finding was considered to have any bearing on his present health the worker was invited to see me, an invitation which was in every case accepted I then explained the significance of the finding, and offered alternative courses to be adopted to deal with the problem, leaving it to his judgment to take the action he thought correct He usually then asked what I would do in such a position, and acted on the course suggested

A note of the X ray and the report was in every case attached to the patient's case-record card kept by my department

THE FINDINGS

Condition	Known	Unknown
Structural abnormality	1	6
Old chest trouble other than tuberculosis	1	9
Presumed old tuberculosis healed of no significance	0	8
Healed, requiring observation	6	6
Active tuberculosis	0	2

(" Known " here signifies that the condition was known to the worker before X ray examination)

One early case detected was confirmed by his tuberculosis officer and recommended for sanatorium treatment Our medical department visitor followed up the case and obtained his admittance within three days Another case detected was not confirmed by his tuberculosis officer and he is still at work under supervision

Twelve cases of quiescent tuberculosis were thought to require supervision and are X rayed at six-monthly intervals in order to detect any early evidence of reactivation

Nine healed tuberculous lesions, not requiring supervision, were discovered and nine other cases show evidence of non-tuberculous disease Two abnormal hearts and a symptomless cervical rib are included among eight structural abnormalities discovered

* * *

The number of cases found agrees tolerably well with the findings of other investigators, considering the small total involved. The sex incidence of those attending is interesting, for in this company there is a preponderance of women The excess of men's attendance is due to two reasons First, intensive recruiting was done in two large shops, which supplied 25% of the total attendances, and it happened that in these two shops the men predominated; secondly, the women were afraid that they might have to strip in public Later on, when this was pointed out to me, I took care to publish the fact that the women were given pyjama jackets to wear, and after that they arrived in larger numbers

The numbers and age distribution of those attending are shown on the graph, and this reveals an interesting disparity in age incidence amongst the younger workers, the boys coming in steady numbers from the age of sixteen, whereas the girls show a gradually increasing attendance until they reach a steady level at the age of twenty This I attribute to the fact that the boys are taught from an early age that as soon as they start work they are independent, whereas the girls learn that they must ask mother's advice until they are married I repeatedly heard that, although the girls were willing to come, the mother had advised against it Later on I advised the girls to make up their own minds and not to ask mother This finding is of importance, for it is among just this sex and age group—namely, girls between 14 and 22—that the incidence of tuberculosis is causing concern Any outside propaganda addressed to the girls will also have to be addressed to their mothers

The total number of suspect cases is probably swollen by the attendance of people who have had tuberculosis and have been discharged as cured from sanatoria and by people whose relatives have suffered or are suffering from the disease The scheme served a useful purpose in that those who feared tuberculosis for one of these reasons but did not wish to draw attention to the fact were able, by attendance at the clinic, to set their fear at rest without going through the (to them) terrible formality of a tuberculosis dispensary, or receiving the unsatisfactory reassurance of a probably hurried examination by their overworked panel doctor

THE WORKERS' VIEWPOINT

The attitude of the worker to tuberculosis needs to be clearly understood He is inclined to hold the medical profession in profound suspicion, and this suspicion is even more keenly aroused if an attempt is made to look after him by a method of which he has had no previous experience, direct or indirect Tuberculosis is to him an inevitably fatal disease, with which he associates loss of work for the long period during which he is dying, whereas observation of his afflicted colleagues tends to show that he could very well have remained at work for another month or two at least Any attempt therefore to get him to take early preventive measures is handicapped When recruiting, I often heard " If I have tuberculosis, I would rather not know about it " This attitude is based on a deep-rooted fear, for the worker realises that if he has tuberculosis and does not know about it he can keep on at work until he drops dead, and then the care of his wife and family will fall on the state and he need not worry about them, whereas if he goes into a sanatorium he lies in bed worrying about his financial commitments

In addition to these financial worries, the worker looks on tuberculosis as an " unclean " disease, like leprosy or venereal disease, and the accusation of tuberculosis is used as a veiled insult as is that of VD

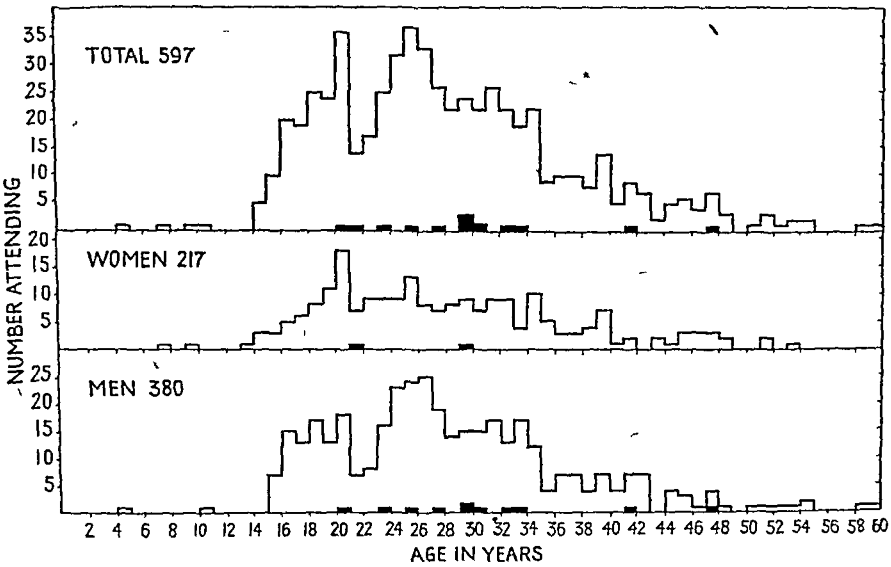
A male worker aged 24 from a mixed shop was suspected by his colleagues, on account of his sallow complexion and a rumour of sanatorium attendance, to be tuberculous This was repeatedly and with innuendo suggested to him, with the corollary added that that being so he was not wanted in his community After some months he broke down under this continued suggestion, he lost weight, slept badly, lost his appetite and became temperamentally nervous Finally, he began to doubt whether his colleagues were not correct, and came to see me Examination and X ray revealed no trace of organic disease, and he returned to his job Inquiry revealed that feeling had been running very high against him, and that the story had originated from a female co-worker who had had an empyema in the past and considered herself unduly susceptible to tuberculosis.

If a man is shown to be tuberculous, he is afraid his colleagues will shun him, and the works doctor must not be seen too often in conversation with a worker suspected by his colleagues.

The financial aspect should be carefully investigated before any large-scale scheme of mass radiography is contemplated. For the success of the scheme full wages should be paid to the worker while he is receiving treatment—that is to say, he should not have his financial commitments in any way affected as a result of taking early sanatorium treatment. To make this possible I suggest the use of a club system whereby everyone who is X rayed subscribes weekly to an insurance fund from which he can receive benefit if he is found to be suffering from tuberculosis.

With his possible financial embarrassment provided for, the worker's next doubt is whether the whole scheme may not be a hoax or a trick for getting him out of the company. A guarantee must therefore be given that, if the radiogram reveals that he is tuberculous, he will not be dismissed permanently, but will be taken back into employment on his return from treatment. It is essential that there should be no reservation in this assurance.

The workers should be told just what is going to happen—namely, that they are going to be surveyed for tuberculosis. Any subterfuge about pictures for the good of their health, or helping in an experimental survey for the good of mankind, is inadvisable (although, if it is pointed out that their cooperation is required for an admitted mass research, they will collaborate willingly just the same, as I proved for myself on another occasion). It is fatal to put forward half truths, since the worker checks up on every statement made to him, and if he can find a doubtful point he will suspect the whole scheme. This applies to any new plan, whether it be about health or wage payment.



Recruitment for the scheme was at first difficult, and had to be done by direct personal approach. This was better received in the shops known to be working under industrial hazard, such as the paint-spraying and metal-plating departments, which are conscious of the dangers to health that their occupation entails. Once a few people from a shop had attended, others followed; also all new employees examined by me were sent for X ray. Later on, when the existence of the scheme was more widely known, notices were posted in the shops, and names quickly obtained.

Sometimes I gave a talk to an entire shop, but this needs to be done carefully. One shop of thirty women whom I approached in the early days became alarmed and as a result of the talk refused to work any longer in a shop where they were exposed to enhanced risk of tuberculosis. For, if this were not so, why had I bothered to talk to them? Such a reaction may well occur when the average mental level of the shop is low and there is no dilution with more mature and balanced workers, from whom the others may obtain reassurance.

THE MEDICAL VIEWPOINT

The results must of course be confidential between the doctor and the worker, not conveyed to a third person without the patient's permission. Permission having been obtained, there can be no objection to notifying the welfare department so that contact with him is not lost. This course was adopted and no worker was forced to adopt any treatment he did not wish to undergo. The strictly professional basis ensures that there shall be no victimisation of any tuberculous person by his employer, and it is this danger which is holding back the trade unions from ready acceptance of any comprehensive scheme.

It is important to inform the worker of the result of the X ray quickly, and so set his mind at rest. A swift report of the result was found to bring in further recruits immediately, whereas delay was apt to kill further response from that shop. Any small abnormality discovered should be mentioned in clear medical language so that the worker can, if he wishes, obtain a second medical opinion on the information supplied. Delayed reporting or obscure allusions are more detrimental to the worker's peace of mind and to the success of the scheme than is a true statement of fact made promptly.

Two other small points are worthy of note: the girls and the men should be X rayed on different days or in different groups, and the girls should be reassured that menstruation is no bar to examination.

Supplementary Notes *by* Miss Clark

During a period when volunteers were required to submit themselves for X-ray examination in order to test the efficiency of miniature radiography, Dr Stanford suggested the inclusion of factory workers, and this offer was welcomed in view of the experience to be gained from a type of subject entirely different from those hitherto encountered in this work. The first problem was that the workers had to come not only at their own expense but in their own time, and therefore after the normal working hours of my department, which meant that two people stayed voluntarily for an hour or more after a heavy day's work. During the winter months this routine was further complicated by the blackout.

BOOKING ROUTINE

It was noticeable that, in spite of the simplicity of the record card provided, help had frequently to be given to the workers in its interpretation. It was also found to be surprisingly difficult to get a group of people to line up in numerical order even when they were provided with numbered cards. This is important as the indirect radiograms are taken in numbered sequence in order to avoid confusion when the completed strip is projected for reporting. Such confusion is of course avoided when the record card is incorporated photographically on the miniature radiogram.

All the records were made in the first instance on these cards and copied the next morning into the departmental record books in order to avoid delay at the time of examination. Data were recorded as to height, weight and chest thickness at the level of the axilla, both on inspiration and expiration, and then these figures were correlated with exposure technique, but after experience had been gained from 2000 subjects, of which this factory group formed a part, it was decided that an expert radiographer who was doing this work continuously could judge adequately the exposure required for each ndividual by simple observation of the development and hest expansion of each one, and it was therefore decided o discontinue these measurements

It was noticed that the physique of these factory workers was in general inferior to that of a previous group of outdoor workers There was a tendency to underexpose the earlier groups, especially the women, who were mainly of very slight physique, but when short exposures were given the breast tissues were not penetrated However, sufficient experience was soon gained to allow of a satisfactory adjustment of exposure

REACTION OF THE WORKERS

The men showed considerable interest in the X-ray apparatus and were amenable in every way, particularly when they found that the examination occupied so little time On one occasion they were asked to submit to a second series of exposures on a trial X-ray unit, and there was no hesitation in doing so, indeed, there was genuine cooperation throughout

The girls needed more discreet handling It is clear that they would not have submitted to appearing without a chest covering, and they were provided with pyjama coats In a number of cases the diaphragm was obscured by corsets and a little tact was sometimes needed to encourage their removal, otherwise, on reaching the exposure stand the corsets were rolled down sufficiently low to miss overshadowing the lung fields, and only in one or two instances was such overshadowing, with compression, noticeable in the radiographic results A few really outsize subjects were encountered, and on these occasions three varied exposures were made to ensure obtaining sufficient density on at least one of the films Occasionally a full-sized radiogram was taken during this first visit to ensure obtaining a diagnostic result, actually the miniatures proved to be quite satisfactory

With children three exposures were made ranging from 10 to 30 mA sec and generally these were all within the range of diagnostic requirements, due to the great latitude of the film employed (HPx) The children presented no difficulty except in the case of a point-blank refusal which we were forced to accept a boy whose two small sisters were quite docile Wives not employed by the firm were usually rather shy about the whole procedure, but it was often possible to examine the "family" separately, either before or after the main group of workers

The films were developed the following morning, and the radiologist reported on the dried miniature by projection during the afternoon The reports were immediately transferred to the cards which were posted direct to Dr Stanford, reaching him within 36 hours of the time the examination was made The trained staff employed consisted of a senior and junior radiographer The booking and marshalling was undertaken by volunteers among the factory workers

It is of interest to note that in one instance a processing fault (drying marks known as tear drops) led to an error in diagnosis (being interpreted as metastases), but the routine direct radiogram taken later enabled the error to be corrected This case served to bring to notice the possibility of such errors being made due to technical defects, but it should be noted that of this particular defect only one instance has occurred in 5500 exposures

TECHNICAL FACTORS

Both miniature and full-sized radiograms were taken on a standard four-valve unit with fine focus rotating-anode tube The camera unit for the miniature work is fitted with a "Contax" camera having a 5 cm f 1 5 "Sonnar" lens, Levy-West yellow-green fluorescent screen with standard lead glass protection, and a stationary radiographic grid

The miniature radiograms were taken under the following conditions, 85 kV peak, 35 to 45 mA sec, and 36 in anode-screen distance, employing Ilford HPx film developed for 8 min in "Blue Label" developer The full-sized radiograms were taken at 57 to 67 kV peak, 20 mA sec and 66 in anode-film distance

Viewing of the miniature radiograms was by projection to a size of ca 6 in square, interpretation was by the two radiologists independently

MINIATURE SCARLET FEVER AFTER A DICK TEST

Hugh R E Wallis, M B
FLIGHT LIEUTENANT, RAFVR

Miniature scarlet fever has been described after the injection of immunising doses of scarlatinal toxin Five hundred times the skin-test dose is the lowest amount recorded to have caused this reaction The symptoms described are scarlatinal rash and desquamation, malaise, headache, vomiting, diarrhœa, pyrexia up to 101° F, and in children urticaria and joint pains[1] There is no record of such reactions occurring after the test dose in a Dick test (0 2 c cm of a 1 in 1000 dilution of broth filtrate) The positive reactions to the Dick test are described by the Dicks[2] as showing "All gradations from small areas of faint colour to intensely red reactions 30–60 mm in diameter"

A WAAF nursing orderly was in contact with a case of scarlet fever in March She had not had scarlet fever herself A Dick test was performed, and a finely punctate erythema which faded on pressure appeared on her forearm and neck and the opposite arm (which was not used as a control) She felt ill and was confined to bed for 5 days She did not vomit and had no temperature throughout The rash lasted for 10 days and then peeled in the characteristic ringed manner A Schultz Charlton test performed rather late was negative, a throat swab showed "Mildly hæmolytic streptococci" No similar reactions were seen among other orderlies and patients tested with the same batch of toxin, and at this stage it seemed possible that she might have had a mild attack of scarlet fever, but the spread of the rash from the site of injection was against this theory

Three months later another Dick test was performed This time the toxin was diluted 50 times, so that she had 0 004 c cm of the standard toxin This was injected intradermally in the right forearm The usual precaution of clearing the needle was taken The next day a punctate rash appeared over the whole flexor aspect of the forearm, and a day later the same type of rash appeared at the base of the neck and on the other forearm A control injection of 0 2 c cm of undiluted heated toxin in the leg produced an irregular area of reddening about 5 cm in diameter which rapidly disappeared A Schultz Charlton test was performed on the right arm, and this showed local blanching The patient's temperature was raised to 99° F, she vomited several times and had a headache She was again in bed for 5 days The temperature fell to normal in 2 days The rash began to peel on the 6th day after injection

This seems to be a clear case of miniature scarlet fever after a very small dose of scarlatinal toxin It would be interesting to see the reaction of this patient if she contracted scarlet fever, or even if anyone attempted to immunise her with the usual doses of toxin

I am indebted to Dr Philip Evans, who searched the published work for me, and to the patient, who consented to undergo the second injection and make herself "a human guineapig," *as she called it*

Evacuation of Mentally Defective Children—The education authorities for London and Birmingham have some vacancies at their residential special schools in reception areas which they are willing to place at the disposal of other authorities who wish to evacuate mentally defective children

Chartered Society of Massage and Medical Gymnastics—The annual congress of this society will be held at BMA House, Tavistock Square, London, WC1, on Sept 18 and 19 The opening lecture will be given at 2 PM by Prof J A Ryle who will speak on the re making of man Afterwards Prof F R Fraser will describe the place of rehabilitation in the treatment of patients, and at 6 PM Lord Horder president of the society, will deliver the founders' lecture His subject will be rehabilitation the part played by physical medicine At 10 AM on the second day of the *meeting Surgeon Lieut* Commander John Bunyan, LDS, will discuss the treatment of wounds and burns by the envelope method and at 11 30 AM Dr Vaclav Benes will lecture on physical training organisation in Czechoslovakia Further information may be had from the secretary of the society, Mount Lodge, Amersham, Bucks

Reviews of Books

Doctor Bard of Hyde Park

J Brett Langstaff New York E P Dutton Pp 365 $3 75

In the middle of the eighteenth century Dr John Bard of New York resolved that his son who wished to adopt the medical profession should have the advantage, which had not been his, of education in a British medical school, and at some inconvenience to his purse he sent his son Samuel to study at the University of Edinburgh, which was at that time rising into great reputation Sam Bard arrived in Great Britain in the year 1763, after having spent five months as a prisoner of war in France He stayed some time in London attending the hospitals and forming connexions with the medical men and others to whom he had letters of introduction, and in the autumn of that year he entered on his degree course with an enthusiasm and assiduity which had their merited reward. He seems to have become during his residence there not merely an accomplished physician but popular and highly respected His principal teachers were Cullen and the two Munros After taking his degree, family ties took him back to New York in 1766, filled with ideas of creating a medical school in his native state He entered into partnership with his father at the age of twenty-four, and had thirty-two years of practice interrupted by the War of Independence but on the whole so steadily prosperous that at the age of fifty-six he was able to retire from the city and live in a house which he had built at the estate of Hyde Park on the banks of the Hudson His retirement was not complete for he often returned to the city to see old patients in consultation with his successor, and in the remaining twenty-three years of his life he was active in organising medical education, and in every scheme which promised medical, horticultural or religious advance At his death there was hardly a sphere of progress which he had not touched To the medical profession in this country his work is chiefly of interest because of the far-seeing wisdom he displayed in the organisation of the teaching of medicine, but to his own generation he was the embodiment of all the virtues which distinguish the beloved physician Dr Brett Langstaff in this account of the lives and times of the Bards, father and son (for John Bard was also a remarkable man) has written a captivating story The one fault—easily remedied in another edition—is the absence of a map of the New York of the time The reader continually hungers for it, and would welcome another of the environs, including the estate of Hyde Park

Psychiatric Dictionary

Leland E Hinsie, MD, professor of psychiatry, College of Physicians and Surgeons, Columbia University, New York, Jacob Shatzky, PhD, research librarian, New York State Psychiatric Institution London Humphrey Milford, Oxford University Press Pp 559 55s

It is natural to stand in awe before the compilers of dictionaries and to wish them judged only by their peers, men who are acquainted with the immensity of the task, but here is a hybrid, half dictionary half encyclopædia, swollen with obsolete terms, psychopathological excursions and thumbnail sketches of syndromes it is impossible to remain awe-stricken before it In it, psycho-analytical bias is carried to the length of including as technical terms any descriptive phrase in the writings of Freud and other analysts, thus "wit, allusion in," "wit, critical," "wit, cynical," "wit, double meaning in," "wit, doubt in," and some further twenty odd varieties of wit, or references to it, all from one book of Freud, are listed as separate entries The pronunciation is recorded of even the simplest words, like egg, first, food, form, dream, maid (defined only as "a virgin man, one who has not had sexual intercourse Obsolete"), however with the exception of "ego" (indefensibly given with the "e" as in "negro") the pronunciation of terms is sound, differences between English and American usage being accepted Proper names in the book are not always so happily dealt with Clouston and Esquirol are mispronounced, MacDougall and Schilder are listed as Americans, yet Kronfeld still as a German, Henry Maudsley is omitted altogether (Mercier is included), Berze is misspelt Berz, and Jack the Ripper is said to have been an epileptic London physician, which will come as news to Londoners The system of cross references leads to such unnecessary entries as "cat, belief one is a", "origin, belief that one is of divine", and surely no-one should be encouraged to find or use "galeanthropy" "uranomania" or other of the monstrous Greek compounds with which the book swarms French terms are well represented but German ones less so Gedankenlautwerden, Grubelsucht and Beziehungswahn are lacking So also is mandala, latah is not mentioned, but miryachit (apparently a Siberian variant) is fully noticed Anosognosia is omitted, as is also its German equivalent "Anton's sign." But the most serious defect in this comprehensive and well-produced thesaurus is its poor treatment of some of the commonest words in psychiatry, such as hysteria, neurosis, schizophrenia or dementia præcox Here the book fails to provide, as it should, a standard which would give some stability to the meaning of terms still confusingly mutable though in constant use

The Handling of Chromosomes

C D Darlington, FRS, L F La Cour London Allen and Unwin Pp 165 8*s* 6*d*

One of the writers of this book has probably done more than any other living man to increase our knowledge of chromosomes, the other has made useful contributions to the technique of studying them They have collaborated to the advantage of fellow cytologists in preparing this authoritative account of the smearing and squashing methods which are nowadays largely replacing the familiar section techniques Some may object to the insistence on the employment of apochromatics for high-power object-glasses, and to call Feulgen's reagent "leuco-basic fuchsin" is a misleading oversimplification The use made of the term "osmic acid" has actually misled the writers of the book into classifying as an acid a substance which forms no hydrogen ions, is a non electrolyte, and only produces salts by a roundabout process The photographic illustrations, which are not very helpful, might have been omitted, thus reducing the cost Such defects, however, are trivial The book is not intended for those who need to understand the physics and chemistry of what they are doing, but for the practical man who wants to make good preparations of chromosomes, and it is full of helpful direct information The calendar showing in what organisms chromosomes may be studied each month of the year is novel and useful

Handbook of Practical Bacteriology

(6th ed) T J Mackie, MD Glasg, DPH, J E McCartney, MD, DSc Edin Edinburgh E and S Livingstone Pp 675 17*s* 6*d*

Almost a hundred pages of this edition are needed to set out the important advances in bacteriological technique and knowledge made in the last four years New methods of diagnosing diphtheria and intestinal infections, the use of *p*-aminobenzoic acid in culture media and the bacteriological examination of the air are among the subjects now discussed The revised section on virus diseases gives the new facts about lymphocytic choriomeningitis and influenza but relevant information about the common cold fits easily into a third of a page and infective mononucleosis is dismissed rather summarily in half a page Some recent bacteriological work is accepted perhaps a little on trust and a note on the recognition of sulphanilamide-resistant strains of bacteria might have been added The book fulfils its intention to serve students, technicians and routine bacteriologists There is a good general introduction, technical methods are selected with care, instructions are to the point and the book is well produced and can still be comfortably held in one hand

---

'Antostab' (Boots), prepared from the serum of pregnant mares, contains 200 international units of mare's serum gonadotrophin per ampoule It is a dry powder and before use is dissolved in the normal saline supplied with it It is given intramuscularly and is recommended for cases of primary and secondary amenorrhœa and other conditions associated with anterior pituitary and ovarian dysfunction.

THE LANCET

LONDON SATURDAY, AUGUST 22, 1942

UTILITY FIRST-AID

THE long-established methods of first-aid taught by the St John and St Andrew Ambulance Associations and the British Red Cross remain fundamentally sound, but they have now to be adjusted to meet the conditions of aerial warfare TRUETA laid down, at Barcelona, the principle that in a blitz casualties must be got to hospital as soon as possible and with the minimum of handling To meet this new demand for simplicity and speed, methods of treatment and terminology have alike been modified Booklets setting out the new point of view have been written by members of first-aid and stretcher parties experienced in raids Lectures have been given to the WVS on immediate aid COWELL has published a five-lecture course for the Home Guard on essential first-aid At a recent course for Home Guard medical officers, H A HARRIS insisted that in the teaching of first-aid all frills and trimmings must be cut out in favour of bare essentials A Home Guard battalion has issued its members with a folder the size of three luggage labels which details the minima of assistance, and provides a casualty label should the man be wounded Another folder[1] designed by KEOGH sets out in a few words and pictures what every soldier must know about first aid In each of the twelve Home Security regions of the country there is a regional training school, originally started for rescue parties, and later expanded to include first-aiders Leaders of rescue, first-aid and stretcher parties now go for intensive training to these schools, so that they may return and pass on the information to their squads Some of the schools are run by the local authorities, some are the responsibility of the regional administration

Details vary in the different training centres, but the principles of the new utility first-aid are accepted in all Thus all are taught that the man who first reaches a casualty should protect him as far as possible from any immediate source of danger such as moving machinery, electric cables or masonry which is threatening to fall The first step in direct treatment is to stop bleeding by dry dressings and firm bandaging Experience has shown that tourniquets are seldom required and it is a relief that the Samway tourniquet, first issued, has now been withdrawn Most of the new writers agree that a tourniquet should only be used for an injury amputation Even pressure points are given less prominence than they were The next essential is to see that the air-passages are clear, rubble and dust must be removed from the mouth and artificial respiration given if necessary, especially if there is reason to suspect coal-gas poisoning The methods suggested are Schafer's Sylvester's, the rocking method and the direct method Cleansing of wounds has to be omitted, because it is usually impossible at the site of the incident, and in any case wastes time Splinting has been reduced to a minimum, which again saves time and lessens handling Application of splints in the dark is a stiff ordeal even for a skilled first-aider and certainly for the patient The patient's suffering—and therefore his shock—will be less if a broken arm is simply tied to the trunk with broad bandages, or if a fracture of the lower limb is treated by placing a rolled blanket between the legs and tying them together The exception is a fracture of the patella, which should *always* be splinted First-aid for burns now consists in covering them with a dry dressing and speeding the patient to hospital Blanketing should be carefully taught—the Wanstead method is now universal—and first-aiders should be well drilled in lifting casualties gently on to stretchers and in loading and unloading ambulances "Careless handling may lose life" is a good motto The danger period is between the time of injury and rescue and of arrival at hospital, the good first-aider will be out to make this interval as short as possible

When many casualties have to be dealt with at one incident the worst must have priority in first-aid and transport thus the first-aider must be able to recognise both the nature of the injury and its gravity The concept is new, and is not touched in any of the standard manuals, but it must be taught and well taught Thus, while teaching must be intensely practical, there must be a clear understanding of underlying principles, particularly among leaders of parties, for they not only have the responsibility of training others but must themselves be capable of quick decision in the more difficult cases Doctors must take full part in instruction, to make certain that the standard is kept at a safe and efficient level This cannot be left entirely to lay instructors, however keen Sense of proportion about cases and treatment can only be acquired through medical training and experience Shock provides a good example of the difficulty it is an exceptional candidate for a first-aid certificate who has an intelligent grasp of this condition, even from his own necessarily limited point of view Everyone should know the essentials of what might be called immediate help "First-aid" has its field and practice defined by usage, and it is to bring out the difference that such terms as "essential aid" and "blitz aid" have been used The standard doctrines have not been upset, only modified, first principles remain unchanged and a sound grasp of them enables well-taught first-aiders to meet emergencies with that intelligence which rule-of-thumb methods can never confer

PROCAINE AND PERCAINE

IN the autumn of 1939 a patient died in Bournemouth because 'Percaine' solution was dispensed by a chemist when the doctor wanted procaine Under "Medicine and the Law" this week there is an account of another fatality, in an Oxfordshire hospital Here, according to a newspaper report of the inquest, the highly experienced hospital dispenser sent percaine crystals to the operating theatre instead of procaine, thinking they were similar substances The surgeon thus came to inject 1 25 grammes of percaine in 5% solution, some ten times the maximum dose, though safe enough if the solution had been procaine A correspondent treating a case of fibrositis was lately told by a consultant that "an injection of percaine or novocain into that area once or twice a week would be helpful" Thinking that these were both proprietary names for procaine, which has many,[1] she ordered a 1% solution Fortunately, after the injection of 6 c cm the patient's reaction suggested that something was wrong and no more was given, so that the patient escaped with nothing worse than a few hours of collapse These examples show that the names percaine and procaine are sufficiently alike to lead to confusion, and though recent correspondence in our columns suggests that the safe dose of percaine has yet to be decided it is roughly a tenth that of procaine Two years ago[2] we expressed the hope that the manufacturers of percaine would sell their product here under the name by which it is known in the United States—'Nupercaine' The makers retorted,[3] with some justice, that the trade mark 'Percaine' was registered in 1918, whereas procaine was not adopted by the BP until 1932, so that it was for the BP to make a change if one was necessary The BP name was no doubt adopted because it was already official in the United States Pharmacopœia, and the BP and USP try to conform in nomenclature as closely as possible The position was considered a year ago by the BP Commission, but it was not then thought possible to take any action The makers, too, are naturally loath to incur the great expense and inconvenience of discarding a trade name which is used throughout Europe and the British Empire and in nine-tenths of the published work on this compound If further accidents are to be avoided either BP Commission or manufacturer must go to much trouble and expense, but the danger is serious, and a friendly discussion between the two would surely evolve a solution

WAR AND THE NERVES

The incidence of neurosis in the civilian population is one of the many respects in which the war has falsified prediction Before its outbreak enormous civilian casualties were prepared for, it was expected that our cities would, like Rotterdam, be overwhelmed with devastating air-raids which would kill many, injure more and drive still more into acute neurotic illness When the air-raids came, they caused fewer casualties than corresponding material damage, and their effect in the causation of neurosis has been, as Dr Lewis pointed out in our last issue, almost negligible If what has been written on neurosis in the Forces is compared with Lewis's findings in civilian life considerable light is thrown on ætiology In both types of population the importance of predisposition has been revealed There had been previous neurotic illness in three-quarters of the neurotic patients presenting themselves to a general practitioner during the worst period of air-raids London has known In as high a proportion the air-raids played a part in exacerbating the illness But while only a quarter of the neurotically predisposed made great improvement or recovered, 70% of the others did It is clear that evacuation has been a powerful method of prophylaxis against air-raid neurosis Most of those who have wished to do so have been able to take advantage of Government schemes for evacuation, and the population that has stayed behind in the danger points has been *self-selected for stability This is one of the* main ways in which the stresses imposed on Service personnel have differed from those inflicted on the civilian The soldier is posted to this or that point regardless of his inclinations, and when he finds things proving too much for him, it is not open to him to get out of it Many of the neurotic pictures shown by the soldier have taken the form of attempts in that direction—absence without leave, amnesic and fugue states, and desertion

The stresses of war are manifold; and if fear has not been very prominent as a cause of illness, that is not so with long-continued worry and other hardships such as the dislocation of family life The break up of the home has been a feature common to military and civilian life but whereas for the civilian it has been, partly at least, voluntary, for the soldier it has been compulsory, and even families where mutual dependance is strongest have been unable to resist separation It is not surprising that many of the men who were fairly adjusted to civilian life but broke down rapidly after enlistment are more than usually dependent on their wives and emotionally tied to their families The same stress when voluntarily or when compulsorily submitted to may have a very different degree of rigour Physical factors *have not been very important in the production of* neurosis The management of our food-supplies has been one of the outstanding successes of war time administration, and defects of nutrition have in general played a minor rôle In the hyperacute anxiety states physical factors have played a larger part Long-continued physical exertion, inadequate food and sleep were largely responsible for the more severe neurotic states seen after Dunkirk, and are associated with exposure and psychogenic stimuli in similar syndromes seen sometimes in shipwrecked seamen These states have been remarkable for their rarity in civilian life—at least in this country in this war, though Mira has reported their frequency in the Spanish civil war Lewis refers to formes frustes of this manifestation For a few days after severe bombing, especially with several sleepless nights, a state of acute but temporary anxiety may develop which passes off with rest and proper care The preference shown by the public for deep rather than surface shelters probably depends on the relief from the noise of an air-raid and its associated feeling of tension, the near-certainty of safety, and the possibility of refreshing sleep

Both age and youth have provided their special problems, although air-raids seem to have little specific effect on the old and the young The break-up and confusion of family life have made the care of those who need it more than normally difficult Institutions have received larger numbers of people enfeebled by age and arteriosclerosis, and in the adolescent there has been a considerable rise in the frequency of juvenile delinquency The contention that our society is built on a basis of stable family life receives confirmation here, and factors that have a disruptive effect on the one cannot leave the other unaffected The importance of this for neurosis lies in its relation to communal morale In the army regimental traditions and company life, and in the navy the ship's company, make for the soldier or sailor a new family unit, and the extent to which he can be reintegrated and his emotional needs satisfied in this way will largely determine his stability, his happiness and his usefulness The proximity of death, hardship and the ubiquity of destructive forces give existence a new meaning In this war, as in earlier ones there is a significant fall in the frequency of suicide New aims for which to live, work that satisfies higher as well as more immediate needs, a tightening of the bonds which draw our community together and unite it with the rest of humanity provide an inspiration which does much to offset the circumstances that lead to discouragement and neurosis

MEASURING SULPHONAMIDE ACTIVITY

THE dosage of chemotherapeutic agents depends on a large number of factors, many of which relate to the host Even their in-vitro action, however, varies greatly under different conditions, and not long ago it was counted an achievement to demonstrate any in-vitro activity in many agents of proved therapeutic value With sulphonamides, the factors governing in-vitro activity have now been largely disentangled The effects of different media have been allocated to definite antagonistic substances, of which *p*-aminobenzoate is the principal one These are now recognised not as extraneous factors sent to plague the chemotherapist but as fundamental to the action of the drugs The sulphonamides are bacteriostatic because they are sufficiently similar in structure to *p*-aminobenzoate to oust it from the essential bacterial enzymes which use it This functional relationship to *p*-aminobenzoate has now been used to give numerical values to the activities of the different sulphonamides The ratio S/P, where S represents the concentration of a sulphonamide necessary for bacteriostasis in the presence of different concentrations P of *p* aminobenzoate, is almost constant for a given sulphonamide and a given organism, and is a measure of the purely antibacterial action of the drug The smaller this ratio—that is, the smaller the quantity of drug needed for bacteriostasis—the more affinity does the drug have for the system it is disturbing Such ratios have now been determined for various organisms and drugs, they have been referred to as antibacterial indices,[1] or as measuring bacteriostatic potency,[2] and their reciprocals have been called bacteriostatic constants[3] They are formally related to Ehrlich's chemotherapeutic index, though the connexion is by computation and not yet by experiment[1]

The results of WYSS and others[4] given in the table, indicate that to both sulphanilamide (the least active drug) and sulphathiazole (the most active) the susceptibilities of seven organisms were in practically the same order, the ratio between the indices for the two drugs was much the same with each organism Thus, as GREEN and PARKIN point out on our opening page, it is a fallacy to think that a particular sulphonamide is specific for a particular organism the most active drug against one organism is normally the most active against all All workers agree in principle with these results but give different numerical values for the antibacterial indices, almost certainly because they adopt different conditions of growth and different criteria of bacteriostasis Thus WYSS and his colleagues observed the quantity of drug necessary to reduce bacterial growth in 16 hours to half its normal amount WOOD[3] judged by the absence of visible growth during 5 days and therefore placed sulphadiazine equal in activity to sulphapyridine, while ROSE and FOX[2] agree with WYSS in putting the activity of sulphadiazine equal to that of sulphathiazole Of the conditions of growth which affect the indices, SCHMELKES and others[5] have shown pH to be of fundamental importance, and have demonstrated that the increase in potency of all sulphonamides with increase in pH is in accord with other evidence that the actual functioning part of a sulphonamide is an anion In solutions of different sulphonamides whose strength is adjusted to give equal activity, the concentrations of anions are of the same order of magnitude[6] It is apparently the group  $-\mathrm{S}\begin{smallmatrix}\mathrm{O}\\ \mathrm{NH_2}\\ \mathrm{O^-}\end{smallmatrix}$ which simulates  $-\mathrm{C}\begin{smallmatrix}\mathrm{O}\\ \mathrm{O^-}\end{smallmatrix}$ at the drug receptor Thus differences between the antibacterial indices of the sulphonamides for a given organism largely depend on the amount of anion in their solutions

DECREASING ACTIVITY →

↓ DECREASING SUSCEPTIBILITY	Sulphathiazole	Sulphadiazine	Sulphapyridine	Sulphacetamide	Sulphaguanidine	Sulphanilamide
Bact coli	27 (36)	43 (100)	450 (100)	534	3960 (1000)	2000 (1610)
Bact aerogenes	45					3220
Proteus vulgaris	55					4000
Staph aureus	53	92	416	534	4570	4660
S typhimurium	92					6650
B acidophilus	133					8000
Ps pyocyanea	184					13330

ANTIBACTERIAL INDICES OF SULPHONAMIDES

Compiled from Wyss et al[4] and Wood[3] Wood s values are in parentheses The figures for different organisms are in the main comparable, but not entirely so because conditions of growth were not inform

In the clinical use of sulphonamides many more factors—differences in solubility, in absorption, detoxication and excretion by the host and even in availability and cost—must be taken into account in choosing the drug best suited to a particular purpose For instance, we choose sulphaguanidine to attack intestinal organisms although its in-vitro activity is low On the other hand, in the choice of sulphathiazole for staphylococcal and mixed infections antibacterial index is the overriding consideration Thus although studies in vitro cannot include all the factors which have to be considered in practical chemotherapy, yet with the present use of defined media they are giving us fairly accurate information of great practical value Animal experiment, it must be remembered, introduces new and unknown factors to the study of human infections

BOOKS FOR POLAND

INTELLECTUAL life in Poland is being systematically suppressed. When the time comes, it will be restored equally systematically, and that is a task in which our country hopes to share. Books can be replaced, and the Poles will themselves revive their nation's learning: anyone who has read Eve Curie's life of her mother knows that. We can at least help to put back the books. At St. Andrews University, which has specially close links with Polish officials and students, a committee has been formed to invite promises of books to be made available after the war. The committee, which includes Sir James Irvine, principal of the university, asks the help of British universities, learned societies and libraries in providing surplus sets, or parts of sets, of transactions or proceedings, standard works, textbooks, journals and periodicals in every department of learning. Individual scholars may be able to promise books from their own shelves, memorial collections or sets of English classics, or subscriptions for the purchase of books. No attempt will be made to accumulate books at present, but a catalogue of books promised will be compiled and handed to the Polish government, which will be responsible for their transport from the donors to Poland when the time comes. Those who will help should write to Mr. N. S. Snodgrass, secretary to the Polish Libraries Committee, The University, St. Andrews, Dundee.

A RARE BONE DISEASE

MELORHEOSTOSIS was first described by Leri and Joanny in France in 1922; Franklin and Matheson[1] give details of a recent case discovered in this country. Leri described the condition as "a flowing hyperostosis of a single extremity," and reported two cases. Since then about 40 cases have been recorded, but few in Great Britain. In 1932 Kraft reviewed 16 reported cases—5 in Italy, 4 in Germany, 3 in America, 2 in France, 1 in Poland and 1 in Sweden. The hyperostosis usually but not necessarily chiefly affects the bones of one limb and its girdle, and is confined to one aspect (lateral or medial) of the affected bones. As a rule the skeletal changes are confined to one side of the body. The X-ray appearance of the new bone is like the wax running down the side of a candle. There are no characteristic physical signs though the patient often complains of pain or disability due to the bone thickening.

The main trouble of the woman of 41, described by Franklin and Matheson, was the great size and weight of her right leg, associated with varicose veins, œdema and recurrent ulceration of the dorsum of the foot. The bone condition was first noted in her eleventh year, when her left leg was found to be shorter than her right; since that time she had worn a built-up surgical boot on the left foot, to adjust the difference between the two limbs. Typical changes were present in many of the bones of the right side of the body, including the skull, several vertebræ, two ribs, the humerus and ulna, several carpals, metacarpals and phalanges, the pelvis, femur, patella, tibia, fibula, all the tarsals and several metatarsals and phalanges. The large number of bones implicated is unusual. The diagnosis of these cases is radiological, the appearance of thickening down one aspect of the bones being due to ivory-like proliferation of cortical bone. The sclerosis seems to begin inside the bone, and the marrow cavity may be obliterated. There may also be deposits of bone in the soft tissues round the joints. Specimens of such deposits or of affected bone obtained by biopsy have been examined, and the appearances vary with the stage at which the specimen is removed, sometimes showing active osteoblasts and normal haversian systems, and sometimes irregular ossification and the formation of dense bone. There is no completely satisfactory explanation; hypotheses have ranged from disturbance of the vasomotor mechanism of the nutrient artery to infection, endocrine disturbance, developmental defect and subperiosteal telangiectasis. Malignancy, tuberculosis and syphilis seem to play no part in any of the recorded cases. No fractures have been reported. Treatment has been symptomatic and X-ray therapy has been tried without success; surgical treatment does not seem to have been tried in any case and no autopsy findings are available. Many of the cases have been found in childhood, or are thought to have started in childhood, being discovered later during routine examination; and increasing numbers of cases are now being recognised. It is possible that a few cases may be discovered in recruits for the Services.

RESEARCH IN IRELAND

THE Medical Research Council of Ireland are somewhat hampered by lack of funds, but nevertheless have used their income of £5000 a year to provide their usual training grants, whole-time and part-time grants for research, and grants-in-aid. In conjunction with Prof. E. J. Conway, Mr. P. J. Boyle, M.Sc., has investigated potassium and electrolyte equilibria in muscle and in the isolated kidney; he has demonstrated that the proximal kidney tubule shows the permeabilities characteristic of muscle. He has also studied potassium equilibria in the yeast cell by a method depending on the displacement of the potassium by ammonium ion, and the same principle has been used by Mr. John Breen, Ph.D., to investigate possible changes in the potassium concentration in yeast. Mr. T. G. Brady, Ph.D., has prepared adenine deaminase in high concentration from calf's intestine. An inquiry of immediate practical interest is that of Dr. Einhart Kawerau into the concentration of ascorbic acid in natural foods in Ireland. Dr. Jame Deeny and Mr. G. L. Murdock, B.Sc., are studying the interrelation between immunity, infection and vitamin C concentration, and are also researching on polycythæmia. The serological studies of Prof. Hans Sachs have a topical application to methods of transfusion, and a reliable technique for blood grouping with higher concentrated sodium chloride solution has been recommended for general typing. He has also investigated peculiar blood samples, irregular iso-agglutinins and polyagglutinability, all of which have a bearing on the reactions which may follow homologous transfusions. Systematic examination of the pelvis has been made in a series of cases by Dr. S. J. Boland with a view to forecasting difficulties in childbirth. Dr. T. E. T. Bradshaw has been studying the excretion of œstrogens and related substances in adrenal disorders. Dr. J. D. H. Widdess is investigating the pathology of the hypothalamus in disease. The pathologists have been particularly lively, Prof. J. F. Donegan being engaged in research into the action of adrenaline on the frog's heart in relation to the production of energy and the storage of potassium. Dr. Oliver FitzGerald has studied problems associated with the presence of ammonia in the gastric juice, and with the diffusion of inulin through various tissues. Mr. M. G. A. Little, F.R.C.S.E., has been studying the effect of autonomic reflexes on the blood-pressure in the spinal animal and Dr. D. K. O'Donovan has gone on with his investigation of the metabolism of hypophysectomised frogs. Studies of the hyperventilation syndrome have been completed, and a new sign for the discovery of latent tetany has been described, based on the response to hyperventilation. In the fields of public health and bacteriology, Prof. J. W. Bigger and Mr. J. Havelock Nelson have found that talc, and some twenty other inorganic substances, make distilled water capable of supporting bacterial life. Miss Ethelwyn M. Mason, Ph.D., and her colleagues have continued to estimate the prevalence of goitre in Tipperary. Prof. R. A. Q.

---

[1] Franklin, E. L. and Matheson, I. *Brit. J. Radiol.* 1942, 15, 185.

O'Meara has made a further study of diphtheria antitoxin during the year Other work supported by the council has been a study of the function of the acrosome in mammalian fertilisation by Prof J Brontë Gatenby, research by Dr J G Waugh into the microscopic and other changes produced by the action of sulphonamides and other drugs on eggs, and the investigation of a case of adrenal cortical hyperplasia by Dr L K Malley Some twenty papers have been published in scientific journals during the year The aid of the council has also been sought by the advisory committee on diarrhœa and enteritis established by the Minister for Local Government and Public Health These conditions have been made compulsorily notifiable since the outbreak reached its peak, in the summer of last year Dr J St L O'Dea, working under the Dublin medical officer of health, will study the clinical and sanitary aspects, and Dr S Sevitt will conduct a bacteriological inquiry into the cause of the condition at the school of pathology of Trinity College, working under Professor O'Meara

CAUSE OF DEATH IN ANURIA

SUPPRESSION of urine is one of the most harrowing and mystifying things a physician may be called on to treat He knows that unless the flow of urine can be re established the patient's life is a matter of days, but why is no urine formed ? What has happened to the renal blood-flow, to the glomerular blood-pressure and the filtration rate ? These are questions few would care to discuss, much less to answer Why does the patient die ? This again is a poser, but at least one can turn to experimental medicine for assistance Hoff, Smith and Winkler[1] have found that if the ureters are tied off or the kidneys removed in the dog there is a rise in the serum potassium from the breakdown of the animal's own tissues They believe that the cause of death is *cardiac arrest due to* potassium poisoning, and have produced reasonably good evidence in favour of this view by following the serum potassium and the electrocardiograms of all their animals They have also injected potassium into normal and anuric dogs and shown that death takes place not when the blood-urea rises to a great height but at or about a critical level of serum potassium , and they have shown also that the changes in the electrocardiograms at death are in all cases those of potassium poisoning There are, however, some unsatisfactory aspects of this theory Hoff and his colleagues admit that in mercuric chloride poisoning an accumulation of potassium is not the cause of death, and the same is true of clinical uræmia Moreover, they have ignored some stimulating work done on this subject more than ten years ago in Hungary Kerpel-Fronius and Leövey[2] came to the conclusion that the cause of death in anuria and uræmia was a rise in the general osmotic pressure of the body to a level incompatible with organised protoplasmic metabolism, and they substantiated their argument by showing that the administration of either sodium chloride or urea to anuric animals accelerated their demise This is an attractive theory, and there seems good reason for investigating the subject further

PAPWORTH

THE report for 1941 makes it clear that the Papworth Village Settlement is progressing in spite of war-time difficulties, and with Sir Reginald Wingate as chairman, Mr Peter Fraser as director, Dr Donald MacCallum as chief MO, and Miss K L Borne as lady superintendent, its future is in safe hands The social and economic implications of tuberculosis are well known—Farr, Newsholme, Hoffman, Biggs and others have repeatedly shown it to be a source of serious financial loss to the community in wage earning power and efficiency, besides bringing many of its victims to poverty or even destitution The triumphs of curative medicine in securing arrest of the disease too often prove Cadmean victories unless the sociological side of the case receives attention "The average consumptive leaves the sanatorium in a state which is little better than an equilibrium between attack and defence"[1] Such a patient is a damaged life He needs care and medical supervision for a long time especially *during the critical* five years following arrest of his disease Put into competition with healthy labour more often than not he breaks down under the strain, his old disease flares up and his last state is worse than the first Sir Pendrill Varrier-Jones coped with this aspect of the tuberculosis problem by the establishment of the Village Settlement and its industrial departments At the same time he provided treatment for all stages of tuberculosis He studied tuberculosis in the individual patient and based his study on clinical experience The treatment given at Papworth is adapted to the needs of the individual patient alike in the hospital ward, the sanatorium shelter or the workshop Varrier Jones realised the protean and fluctuating nature of tuberculosis This broad outlook is the secret of Papworth's success

BLOOD TO THE FEMORAL HEAD

THE management of fractures of the femoral neck is rapidly becoming standardised , in most clinics medial fractures and many of the lateral fractures are treated by the insertion of a Smith-Petersen pin supplemented in some cases by a bone graft The use of screws, multiple Kirschner wires or bone-grafts alone appeals to a minority but all agree on the necessity for accurate reduction and reconstruction of the femoral neck by an extra articular operation under radiographic control As the variable factor of mechanical accuracy approaches the ideal the end-results will come to depend more and more on the initial injury to the blood-supply of the head That success or failure in obtaining union after a careful operation is determined largely by this element of avascular necrosis has been emphasised by de las Casas,[2] who deprecates the use in all cases of the Smith-Peterson operation He concludes from injection studies that the ligamentum teres contributes little or nothing to the blood-supply of the head, most of whose vessels run medially from branches of the circumflex arteries The more medial the fracture the greater is the danger of complete severance of these branches, and if the fracture is nearer the head than the middle of the neck avascular necrosis becomes a strong probability In more lateral fractures the blood supply may be inadequate for union even if the head has survived, and many cases that do unite develop a severe degenerative arthritis as a late complication of necrosis For these reasons de las Casas does not attempt the reconstruction of medial fractures but excises the femoral head as primary treatment in all cases, adding an abduction osteotomy at the lesser trochanter whenever the patient's condition allows Lateral fractures are treated by bone-grafting except when the Smith-Petersen pin—which he thinks contributes to the danger of necrosis—is used , he reserves this as a rapid procedure for feeble patients

Many will consider these views on treatment of medial fractures both too sweeping and too pessimistic, for there is evidence[3] that, in good hands, the pinning operation secures bony union in about 70% of cases At a discussion on avascular necrosis at the Royal Society of Medicine[4] Watson-Jones said its incidence after the closed operation is only about 15%—though this is doubled when an open exposure involving capsular damage is employed—and that the insertion of the pin increases neither the frequency nor the severity of this complication Brailsford,[4] however, considers that the destructive changes in the hip-joint following necrosis are worse after pinning than with external splintage, since a false sense of security encourages too early weight-bearing The pin itself may cause added vascular damage Both agree that the relative density of the head which is the earliest radiographic sign may be masked by early functional activity which minimises the contrasting disuse rarefaction of the rest of the bone Recognition of avascular necrosis, which ought to be made at 6–8 weeks, may thus be delayed for many months, and it is important therefore to keep patients quiet in bed for 3 months after the operation This is probably of some positive value in preventing further injury to the blood-vessels of the neck during too early walking, when the pin is the only form of support

[4] See *Brit med J* 1942, i, 503

It is well to be reminded that there is a biological as well as a mechanical side to this problem, and no one will deny de las Casas's thesis that each of these fractures must be treated on its individual merits and not as just another opportunity for what may be a strikingly successful operation

THE RIDDLE OF ARTERIOSCLEROSIS

Is the problem of arteriosclerosis the modern equivalent of the age long search of the alchemist? Are we dealing here with that strange conundrum, the secret of senescence? Observations accumulate and refuse to fit into any coherent design, and perhaps we are still only at the stage when relevant material should be noted and filed for future reference The latest contribution to the subject comes from a large department-store in New York, where Lake, Pratt and Wright[1] have studied the incidence of arteriosclerosis and varicose veins in 536 employees of both sexes over 40 years of age They divided these into four occupational categories those sitting (e g, typists), those standing (e g, lift operators), those walking (e g, porters), and those climbing stairs (e g, delivery men—it seems that nearly 10% of the employees climbed stairs "most of the time") The lower limbs only were examined and conclusions were based on a history of pain on walking relieved by rest, inspection of rubor on dependence and pallor on elevation, palpation of the arteries and veins, oscillometric studies, and radiological examination of the soft tissues Many results were invalidated by the smallness of the subgroups, but a few are striking Thus the total incidence of arteriosclerosis was 35% (46% for men and 20% for women) and arteriosclerosis appeared to develop a decade later in women than in men Among the younger men (age 40–49) work which demanded stair climbing seemed to produce a significantly higher incidence of arteriosclerosis (38%) than sedentary or standing work (21%), but this difference did not apply to women The men had a much higher incidence of calcification in the arteries than the women, but the use of alcohol or tobacco could not be shown to have any correlation with the presence or degree of arteriosclerosis As might be expected, the incidence of arteriosclerosis was higher in hypertensives than in those with normal blood-pressure, though it is noteworthy that 63% of the men with hypertension had arteriosclerosis compared with only 28% of the hypertensive women The relation of varicose veins to arterial disease proved interesting, 73% of subjects over 60 years had varicose veins, taking all subjects, 67% of women who had never been pregnant had varicose veins compared with 41% of the men Women who stood or walked showed a much higher incidence of varicose veins than those who sat—a difference not found among the men In both sexes there was a higher incidence of arterial disease in those with varicose veins, but the correlation was not statistically significant in women, though it was in men The sex difference in the incidence of calcification of the arteries can be correlated with the observation of Ludden, Bruger and Wright[2] that in female rabbits fed with cholesterol the development of hypercholesterolæmia was inhibited, and the deposition of cholesterol in the aorta prevented, by the administration of testosterone propionate or œstradiol dipropionate, whereas in male rabbits no such inhibition was found This suggests that the relative infrequency of arteriosclerosis in women may be partly due to the presence of the ovarian hormone Tobacco and alcohol have once more been cleared of responsibility for arterial disease though without prejudice to the possibility of tobacco's vasospastic effect in patients with obliterative arterial disease

SAVED MILK AND SAFE MILK

CIRCULAR 2669 of the Ministry of Health is solely concerned with milk as a perishable food Its aim is to reduce loss of milk from souring or tainting and to safeguard the keeping quality of bulked market milk It proposes to do so by instituting a system of examinations of milk using certain standard tests These as far as practicable will be carried out in trade laboratories but under the control and supervision of the provincial dairy bacteriologists, who are already in existence These bacteriologists will arrange for frequent check tests to be made by their staff The actual tests to be used are not disclosed Three categories of producers' milk are proposed—"market" milk, satisfactory for the liquid milk market, "salvage" milk unsuitable for the liquid market, and "rejected" milk, to be returned to the farmer Salvage milk will be at the disposal of the Ministry of Food, who will whenever practicable arrange for its salvage, manufacture or disposal, and who will determine the price to be paid for it (If salvage is impracticable the milk will be returned to the producer) While the scheme will mainly be applied to depot or creamery bulked milk all supplies of milk, including designated milks, delivered from farms will be liable to test This scheme is however additional to existing regulations including those for designated milks, and the minister asks local authorities to maintain their work under these various orders and regulations The advisory work will be undertaken by the county war agricultural executive committees through their demonstration subcommittees The scheme involves price differentiation on a quality basis, prices being decided by the Ministry of Food in consultation with the Milk Marketing Board Milk legislation is already very complicated and this scheme adds to the burden already on the shoulders of the farmers and milk producers That it should be necessary is part of the penalty to be paid because Government departments have shirked handling the milk problem firmly Procedures have been adopted which do a little good at the expense of much administrative effort, but never go to the root of the problem The latest Government action is intended to conserve milk from becoming unsaleable, but leaves untouched the need for making it safe from the risk of spreading disease, in spite of urgent medical representations Much of the extra milk now allocated to young children and school children is just "milk," like Hamlet's father unanel'd, no reckoning made but sent with all its imperfections on its head Some part of the increase of human tuberculosis during the present war may turn out to be due to the greater consumption by children of milk infected with the bovine bacillus Where pasteurisation of milk for schools is impracticable it would probably be better to supply dried milk

In England Now

A Running Commentary by Peripatetic Correspondents

WHETHER or not there is any alteration in medical practice after the war, I would advocate the compulsory holding of a DC—Diploma in Consultancy—for anyone proposing to take up consulting practice; before admission to the examination the candidate to be not less than thirty and to have had at least two years in general practice including contract work. My board of examiners would consist of three general practitioners to every one consultant, and two attempts only would be allowed. The examination, to be held not more than twice a year would entail first a half-hour paper, which would include the writing of two letters to doctors in proper style for hypothetical referred cases, marks to be given mainly for practicability of suggestions and questions such as "What would you say to (*a*) the patient and (*b*) the relatives if your findings were such and such?" The other part of the examination would be a pretty stiff viva, 25% at least of the marks to be given for general appearance, manner &c. "Relatives" would be interviewed, awkward prearranged questions by "patients" would have to be answered and a "talk about the case" would be made with one of the examiners acting as the GP. I haven't thought what I would do with the proceeds of the examination; perhaps if the fees were fairly high there would be enough to start a Consultants' Benevolent Association—run by GPs.

* * *

I saw a crap game in the tube today. The last time I saw one was in the Pullman wash-room during a wearisome journey on a public holiday from New York to one of the Canadian cities. The train started soon after breakfast and arrived sometime the same night; I don't know quite when for I was not allowed to be present. Although the United States was our ally, British subjects not resident in the Western Hemisphere were classed as aliens and treated as such. Regulations required that travel papers should be handed to officials who are responsible for advising the immigration officer if the said alien wants to leave the country. With the full assurance that everything was in order I started off for Canada. The snow got deeper, the daylight faded, the passengers left one by one and for many miles only a few remained. The tedium was relieved somewhat by the intelligent conversation of the coloured porter in the car. He was not the only man I met in the United States who seemed quite unaware of the real conditions in England in war-time and the sacrifices demanded of, and willingly submitted to, by our general population. The supposedly intelligentsia were amazed to hear in detail about things we regard as commonplace—rationing, taxation, and how John Citizen spends his day. It is comforting to know that steps have been taken to promote a better understanding in the United States of the British outlook today. Canada is of course, as war minded as we are, anyway in the Eastern Provinces.

The train stopped at the frontier. A squad of Customs and Immigration men descended on me. The Customs, observing my nationality, made their examination the merest gesture, I suppose so that they could give pride of place to Immigration. Immigration was very fierce as I deferentially handed over such identification papers as I still possessed. The man seemed rather undecided about me, so I explained that additional papers should be in his possession, and actually he had to my knowledge been officially advised that I wanted to cross the frontier. Other officials now joined my questioner and after a brief consultation they announced that I must accompany them for inquiries. Despite the fact that there would be no further train for 24 hours I was neatly assisted from this one realising that I was more or less under arrest on suspicion. Traditional English teaching is to "come quietly" which I did feeling that it was wiser to accept the inevitable gracefully. One interest of life is to appreciate skill in others. The polite firmness with which I was escorted through the darkness across the station yard and right into a waiting car was unexceptional and a breakaway would have been impossible. There was a drive of about a mile to the frontier post opposite the entrance of which the car drew up so that its door opened against one side of the entrance while the open side was filled by a man who emerged from within. "I see you've got someone," he said to my guardian. Evidently a catch relieved the monotony of frontier life particularly on Christmas night when business was slack.

After further questioning and scrutiny of my papers it was announced that as immigration headquarters had not yet notified the frontier of my existence I should have to wait until the next day, if not longer, till the business was regularised. I explained that I was not travelling for my health and that I was due for important meetings the next day. Later one friend whom I spoke to on the telephone and with whom I had an appointment offered to journey through the night to identify me. His offer had to be refused because nothing short of strict compliance with regulations seemed to be of any avail. A little disquiet was now softening the general attitude to me, and as a concession I was told that I could spend the night at the inn if I preferred this to a wooden bench in the frontier post, so I was driven in a taxi to a nearby village where I checked in at the local. This establishment was run by a French Canadian who took the circumstances of my arrival as a matter of course; he did a regular trade with people stranded like myself. We conversed in both English and French but I realised then and subsequently in that region that the French they speak differs materially from that spoken in Europe not so much in the words perhaps but in their pronunciation. After being allotted a pleasant little room, even in this outlandish spot fitted with running water and other refinements, I adjourned to the bar, there being nothing else to do. The landlord had already announced that there was someone from London around so conversation and questions soon started. I was the second European within a few days to be stopped. It was easy to recognise who the other man had been—a Frenchman I had met on various previous occasions. He must have created an all-time record by his journeys in Europe and across to and into the United States with only a sheet of notepaper for credentials yet he met his match here, far removed from war or thoughts thereof.

A special brew of the pub was a rum punch called Tom and Jerry. The recipe and name, I was told, came from Huntingdonshire England where it was said to be a special Christmas brew. It had been introduced to these parts by the early settlers. So far I have had no chance to check its history, but I can testify to its soothing qualities in time of trouble. I was rescued next morning.

* * *

When I was a student like many another I grappled with Cut and Comeagain's Manual—one might almost say Bimanual—of Surgery. I had to transpose C and C's formal diction into a picture except when they provided one for me, and then I had to reduce that picture to words of my own more simple vocabulary. All this in order that I might be able to answer the examiners' questions clearly and to the point but above all and everything to answer the questions. Ten years later when I was surgeon on a steamer I was sent for by a passenger in one of the cabins de luxe and found he was none other than the great Comeagain himself, retired and on a world tour. For some weeks I felt myself one of the elect in that I was treating this great man, who was kindness itself to me and told me many anecdotes, some of them even derogatory of Cut. It was as though while out for a country walk one happened to climb Mt Olympus and running into Zeus was not only asked to prescribe for him but also was regaled with pleasantries, "Have you heard this one about Apollo?" The conceit engendered by this lofty association must be my excuse for daring to criticise the interim report of the BMA Medical Planning Commission on a fundamental point. Before we have read six lines what an amazing thing do we discover! The terms of reference, the very charter of the commission's existence, says that they are "to study", not a word about suggesting or planning just to "study war-time developments and their effects on the country's medical services both present and future." Though how in the name of Heaven one can study future events I don't know. Speculate about yes, but then they are not licensed to speculate, only to study. This foundation-stone sentence is certainly a flimsy basis for changing the whole structure of British medicine. It is like getting an order from the coroner to perform a necropsy, and going on to hold the inquest oneself, arrange the funeral, and then issue a majority report in favour of "Nearer my God to Thee" on the tombstone, while the minority favours "Peace perfect Peace." Blue pencil, please.

* * *

He has one of those lean, immobile faces the expression on which seems to say "Go on. Impress *me*. Make *me* laugh—if you can." When he looks up or down or sideways he appears not to move his head at all but his eyes, restless and steely-blue, miss nothing. By occupation he is a doctor's man of all work and this involves a good deal of rabbiting and the care and management of shooting dogs which he trains himself. His present dog is a sound worker, obedient and devoted to a master no less devoted to him though sparing of caresses or praise; indeed, in conversation he usually refers to the dog as "that black beggar"—especially when the dog very sensibly jibs at working out some particularly thick and uninviting briar-patch through which his master stoically plods his way beating and stabbing with his long stick. Seeing him one day stand stock still with head slightly bowed I guessed that he must be looking upward at something, so I worked my way round him till I could see his eyes. Following the direction of his gaze I saw it was riveted on a crow's nest fixed in a fork near the top of a tall oak. To those with a gamekeeper's outlook on life crows are anathema. "There's mebbe a brood o' young 'uns there," he observed and, without more ado, strode across and began to climb the tree as nimbly as a cat. In a matter of seconds he had reached the nest and reported it empty but on general principles he overturned it before climbing down. I congratulated him upon his agility but he made nothing of it. "'Tis all 'coordin' to what you'm used to," he said. I only hope that I shall be able to climb half as well when I'm 62.

* * *

Morale is most important in a hospital ward, and it has always puzzled me why it varies from time to time and from place to place. No doubt the mumbo-jumbo men know the real explanation, but the simple-minded surgeon must look for simple explanations. Everything in this hospital is done by orderlies, who before the war were anything from clerks to coalminers, but now, clothed in masks (see MRC War Memo No. 6) and armed with forceps, maintain a terrifyingly inaccurate but so far successful asepsis in the wards. They are keen and cheerful—they organise a football team, a dance band, and a concert party. The last is my great rival and I often have to remind men and even colleagues that we are a hospital and not an academy of concert-party art. But I am not hostile; I go to their performances and await with horror the man who has sung the same sentimental song ever since the war started; and I revive the thrills of a child at the circus when we come to the strong man and acrobat turn. These wonderful men seem able to do anything; especially do I like Private X who solemnly turns somersaults across the stage holding the *Times* in his hands and pretending to read it. Last night I was chatting to the night sister. "Yes," she said, "I heard all the patients shouting early this morning, so I rushed into the ward. I had sent Private X to do a fomentation at the end of the ward. He was holding the foment in his hands and doing somersaults down the ward as fast as he could and everyone was sitting up in bed cheering him." I laughed. "But," she cried, "what's the use of his wearing a mask and gown if he does that?" But the morale is good in that ward.

* * *

I was asked to help clear out the medicine cupboard of an aunt recently dead. She had been an old lady of meticulous habits and everything was neatly labelled. On one bottle, lest there should be any possible mistake, she had carefully printed, "Cascara, I think."

* * *

We were on a ward-round with a number of GPs, and the patient had either ascites or an enormous cyst. Two of them began conferring; eager to anticipate a question, I edged across in time for the last sentence. "Yes, my goodness," said one of them, with more interest in the patient's household arrangements than I could readily countenance, "*she'd* fill her bath."

MEDICINE AND THE LAW

Procaine and Percaine

A RECENT inquest at Banbury revealed a dispenser's mistake. She received a written slip from the theatre sister asking for one gramme of procaine. Thinking procaine and 'Percaine' to be similar substances, she used crystals from a bottle of percaine and labelled the solution "procaine." Giving evidence before the coroner, she said that she had heard of percaine but had never dealt with it in the pure drug form; she was so convinced that procaine and percaine were identical that she did not consult any book.

The patient had been admitted to hospital after an accident; his chest was crushed and skin-grafting was necessary. For the third of these treatments, four months after the accident, the surgeon decided to use a 5% solution of procaine as a local anæsthetic and asked the sister for this. The operation was finished by 3.15 P.M., but the patient almost immediately had a convulsion and followed it with six more in the next quarter of an hour; he was dead before 4 o'clock. Dr. Alastair Robb-Smith, of the Radcliffe Infirmary, Oxford, conducting a post-mortem examination, found death was due to heart-failure and shock. The solution in the bottle, on being analysed, was found to be a solution of percaine. The witness explained that the normal maximum dose of procaine was two grammes; the surgeon had injected 1.25 grammes, a perfectly safe dose if the substance had been procaine. Percaine had a quite different action, more powerful in its anæsthetic properties and more toxic; the safe dose for an adult was reckoned as 0.12 gramme. The patient had been given ten times the maximum dose; this was the immediate cause of death. Dr. Robb-Smith said it was unfortunate that names so similar as percaine and procaine should be employed.

Shock due to Noise

To be negligent is to take the chance of having to pay damages to anyone who suffers injury in consequence. If a negligent motorist (the negligence which occupies the judges' attention is usually negligence in the use of a motor vehicle) breaks a pedestrian's leg, the case is easy. If the injury takes the form of nervous shock, if there has been no physical impact but merely the apprehension of an impending or immediate accident, there may be a question whether the damage is not too remote to be actionable—whether, in fact, the motorist could reasonably have foreseen this particular consequence and his want of care. In Bourhill *v.* Young the House of Lords has lately decided an interesting case of this kind. The plaintiff suffered from shock merely through hearing the squeal of the brakes and the crash of the colliding vehicles in the distance.

Mrs. Bourhill, explained Lord Thankerton, was a fishwife who was travelling on a tramcar near Edinburgh on Oct. 11, 1938. The tram stopped at a stopping place just short of a crossroad. She alighted and went round the near side of the tram to lift her fish-basket from the off-side of the driver's platform. A motor cyclist, travelling at an excessive speed, was going in the same direction as the tram; he collided with a motor car at the crossroads, was thrown on to the roadway and received fatal injuries. Mrs. Bourhill neither saw nor heard the cyclist previously; she knew nothing of him until she heard the sound of the crash when the vehicles collided. At that moment she had her back to the driver's platform and the driver was helping her to get the basket on to her back and the broad leather strap on to her forehead. The scene of the collision was about 45–50 feet away from her. After the motorcyclist's body had been removed, she approached and saw the blood left on the road. Her case was that as the result of the collision she wrenched and injured her back, was terrified and suffered severe shock; she was about 8 months pregnant and gave birth to a child on Nov. 18 which was stillborn, she alleged, as the consequence of her injuries. The trial judge took the view that the noise of the accident caused a nervous shock but that she had not proved that the stillbirth or the injury to her back resulted from the shock or her immediate reaction to fright due to the noise. The shock disabled her from carrying on her business for a time; there was thus a sufficient finding to raise the question of the dead motorcyclist's liability The problem was the extent of the latter's duty towards other passengers on the road Clearly he must ride with such reasonable care as would avoid the risk of hurting anybody whom he could reasonably suppose likely to be injured by his failure to use reasonable care It is settled law that the injury may include injury by shock without physical impact or lesion There must, thought Lord Thankerton, be an area of potential danger which the cyclist ought reasonably to contemplate as likely to exist in consequence of his negligence Was Mrs Bourhill within that area? Lord Thankerton was clearly of opinion that she was not

Previous leading cases have arisen out of some carelessness in the control of a motor vehicle A lorry-driver leaves his lorry imperfectly braked and unattended at the top of a hill It starts off downwards and a mother, seeing the uncontrollable monster gathering pace, suffers shock from fear for her child who, she thinks, is playing in the road below But in the Bourhill case the motorcyclist had his cycle under control, though he was exceeding the proper speed Did he owe Mrs Bourhill any duty? She was not within his range of vision, the tram obstructed any view of her, he was well past the tram when the accident occurred Ought he to have thought that his machine might ricochet and hit her or that falling glass might strike her? Lord Thankerton thinks the motorcyclist need not have imagined any such contingency Mrs Bourhill based her claim merely on sound, not on apprehension of an impending collision The volume of noise afforded no ground for argument A plaintiff claiming damages for negligence must establish some breach of duty on the defendant's part Mrs Bourhill failed to do so She therefore lost her case, and the trend of judicial decisions (which had been favourable to plaintiffs in these cases of shock) for the moment suffers a setback

CUTTING DOWN QUININE

In March of this year the Ministry of Supply announced that supplies of quinine in Great Britain were adequate and would last for some time, and that steps were being taken to ensure that sufficient stocks would be available for the next year or two Most of the world's supplies come from Java, however, and it has now become necessary to husband our stocks rigidly so that malarial patients can have first call on them Under his emergency powers the minister has arranged that, from Aug 13 onwards, cinchona, cinchona products and synthetic substitutes will be controlled The controlled material thus includes any bark (whether whole, ground or crushed, or in any other form) from any variety of *cinchona* and any preparation made from it, any alkaloid derived from such bark, and any "salt of any alkaloid, any totaquina or quinetum, any mixture of cinchona alkaloids, any cinchona febrifuge, or any synthetic product or material which according to current medical opinion is a specific for malaria The controlled materials will only be supplied to the following anyone holding a medical prescription for a quinine preparation, any hospital authority, retail pharmacist or doctor, provided he keeps within a fixed limit (calculated as quinine, 25 oz), any patient holding a medical certificate or a document from a Government department stating that he has, or has had, malaria, anyone requiring it for use as part of the medical stores of a ship, any Government department, and anyone authorised to obtain material on behalf of the Minister of Supply Doctors are at liberty to write prescriptions containing quinine for any patient, whether malarial or not, whom they consider needs it, but since it is essential for the treatment of malaria, the minister is confident that doctors will not order it for colds or other ailments which can be treated with alternative remedies Quinine has also been withdrawn from many preparations, proprietary and other, in which it was previously used For some time it has been left out of tonic water and quinine drinks and it has already been omitted from Easton's syrup All holders of stock containing 25 oz or more of quinine must notify the Director of Medical Supplies, Ministry of Supply, Portland House, Tothill Street, London, S W 1 Copies of the order may be obtained

Letters to the Editor

DIPHTHERIA IN INOCULATED PERSONS

SIR,—Dr Glover and Professor Wright, in their analysis of the results of diphtheria immunisation in Liverpool, say that "the response of the people of this city to the offer of inoculation free of cost has been most disappointing" Their disappointment must be shared by doctors all over the country If, however one compares the meagre insignificance of the propaganda on behalf of diphtheria immunisation with the prominent and ubiquitous boosting of So and So's infallible remedy for such and such one realises why the "offer" of free immunisation often never reaches, or at least fails to impress the public Must the arts of propaganda be used solely to boost worthless placebos for the profit of their manufacturers or would it be justifiable to use these well-tried methods for the public good? Better publicity is one necessity, another is ready availability The striking difference in incidence of immunisation among school-children and among preschool children (31% and 6% in the paper quoted) is no doubt due to the fact that arrangements are often made in schools for the inoculation of its pupils, whereas the mother herself is responsible for taking her younger children to a clinic, which may be some way off, up to five times (the actual number of attendances differs in the various clinics) Finally, many doctors themselves are indifferent to the matter If every doctor, nurse, health visitor and welfare worker impressed on every parent with whom they had professional and social contact the urgent necessity of diphtheria immunisation it might in time become a social disgrace to have a child known to be unprotected against this deadly disease

West Middlesex County Hospital   PATRIA GAIRDNER

TUBERCULOSIS IN NURSES

SIR,—I should like to comment on two points in your correspondent's report from the press gallery (*Lancet*, Aug 8, p 172) In regard to the shortage of nurses, is it not time that the state made some provision for those nurses unfortunate enough to contract tuberculosis in the performance of their duties? Here are two examples of what may now become of them

A state registered nurse contracted tuberculosis while nursing in a well known chest hospital some 9 years ago She went to a sanatorium for treatment and after some time was put on the nursing staff She crocked regularly each year, and 2 years ago she was told that she would never work again The medical superintendent of the sanatorium was kind enough to say that she might make her home there for the rest of her life Her only money is 2*s* a week total disablement benefit This is all she has to provide herself with luxuries and necessities—even clothing

Another contracted this disease in a general hospital at the age of 21 or 22 She also went to a sanatorium, and 4–5 years ago was told that she could not work again She accepted the offer to stay on at the sanatorium for life, and her only income was 3*s* 6*d* a week total disablement benefit She was really entitled to 6*s* but 2*s* 6*d* had to be allowed to accumulate because she was in a hospital (see Ministry of Health Leaflet No 35, 1938) The fact that she would never leave the sanatorium alive made no difference to her approved society After her death I saw an advertisement stating that there was an estate of £25, and asking for next of kin to claim it This money, had it been paid to her, would have made her life a little easier

Knowing of these cases, and many others, I feel it unjust to direct nurses lightly into this work, which may

---

Continued from previous colomn

from H M Stationery Office It is encouraging to know that thanks to the enterprise of an American officer, a quantity of cinchona seed has been safely brought from the Philippines A correspondent in the *Times* of Aug 15 recalls that Lieut -Colonel A F Fischer, who was chief of the Philippine Forestry Service for a long time, introduced the cinchona plant to those islands During the defence of Bataan and Corregidor he supplied quinine to the troops, and when the situation became critical he flew to Australia with large supplies of selected seed after all, end in the plight outlined above I am not suggesting that the risk of infection is great—it is certainly no greater working in a sanatorium than in the tuberculosis ward of a general hospital—but it does exist and it is time some financial protection was offered to nurses undertaking this work It is ridiculous to compare them to fighting men who, if incapacitated, do at least get some pension

It is lamentably true that " the rehabilitation of the tuberculous patient has not been sufficiently provided for in the past " and it is to be hoped that " the maintenance and subsidising of tuberculous patients from the time they leave the sanatorium till they return to full employment " may become so at some *early* future date When a patient leaves a sanatorium, invariably not yet fit for work, if he has no home he must apply for public assistance I doubt if it is generally known what rudeness *and cruelty is meted out to such patients, even* when they have a letter from the almoner of the hospital where they are having treatment Most relieving officers are clearly ill-fitted to discharge this duty

A girl who applied for relief with such a letter was asked by the committee what money she had in her bag On saying that she had 5*s* she was told that she must apply when she was destitute The 5*s* had been loaned to her and she was in fact, penniless After an unpleasant scene during which she was told that it was her duty to get well as soon as possible and not be a drain on the community, she was allowed 25*s* a week, out of which she had to buy 2 pints of milk a day if she followed the advice of the hospital The sum was paid but the manner in which she was treated was so unpleasant that she returned to her lodgings with a temperature of 100° F saying that she would rather work and die than remain on PA In fact, she crocked again within 6 weeks or so and returned to hospital, costing the state a good deal more than 25*s*

I feel this sort of thing should be brought to the attention of the medical world

Harrow E D ANDREWS

THE MILK FACTOR IN CANCER

SIR,—Few indeed must be the themes in biology and medicine which have entirely escaped discussion in the older records, even—perhaps usually—when evidence was scanty or lacking Sir Alfred Webb-Johnson's letter in your issue of Aug 8 shows that the milk factor in the transmission of disease of sucklings is no exception, since the subject had occupied the attention of philosophers from very early times More specific conjectures, relating to a milk factor in the transmission of cancer-susceptibility, appear however to be rare, so that the following may be of interest (F -J -Leon Rouzet, *Recherches et observations sur le cancer*, Paris, 1818, pp 317–8)

" L'héredite du cancer une fois reconnue, on voit de quelle importance il est de remettre l'enfant nouveau né a une nourrice etrangere, lorsque la mere a presente, soit avant, soit pendant la grossesse, quelques symptômes cancereux, puisqu'il n'est guere douteux qu'elle ne communiquât a son nourrisson en l'allaitant cette disposition au cancer a laquelle il avait peut-etre echappe pendant l'epoque de la gestation "

On the same subject Rouzet also refers the reader to Portal (*Maladies héreditaires*, p 74 et seq , and to Petit's article in the *Dictionnaire des sciences medicales*

London, S W 3 ALEXANDER HADDOW

SUBLINGUAL THERAPY IN ADDISON'S DISEASE

SIR,—Having read Dr Andrew Wilson's article of June 27 with much interest I would like to quote one case in which we tried sublingual therapy

A tractor driver, aged 17, working on a farm, was admitted to hospital on Jan 16 complaining of anorexia and vomiting He had been well until 2 weeks previously when his symptoms developed rapidly with well marked lassitude, but no shivering, gain or cough, and no headache or giddiness On admission he was extremely apathetic and drowsy, and was deeply pigmented a homogeneous brown, especially on hands, face, axillary folds and nipples BP 60/45 mm Hg The condition of his mouth was very bad and there was much pus on the tonsils He was treated with 'Eucortone' 10 c cm t d s intramuscularly and rectal saline when the vomiting was most severe By Feb 10 there was considerable improvement with no further vomiting and pigmentation, drowsiness was definitely less His BP was now 96/64 mm Hg The eucortone therapy was then altered to 'Doca' 7 5 mg daily intramuscularly On Feb 23 his general condition was further improved, BP 105/64 Additional salt (15 g daily) was being added to his normal diet Doca sublingual tablets were then substituted, and he was given one 2 5 mg tablet five times daily (12 5 mg daily) He was instructed to keep the tablet under the tongue until it was fully dissolved—not to suck it During the next week he developed an obstinate stye of his right eye He became a little more drowsy and the pigmentation became rather more definite, doca 5 mg daily by intramuscular injection was therefore given in addition to the tablets Very soon there was an improvement and by March 18, when the stock of tablets was temporarily exhausted, his BP had reached 122/86 The patient had put on weight and was feeling very well, though he was still kept in bed For 6 days, the doca intramuscular injection were cut down to 5 mg on alternate days but almost at once there was a change, with the onset of sore throat and pyrexia The injections were then made daily but by March 29 the BP had fallen to 96/64, temp 101° F There was more pigmentation, much nasal secretion and severe asthenia The injections were increased to 10 mg daily, with a rapid response in the general condition This dosage was maintained and the subsequent improvement was steady By April 23 (3 weeks later) the BP was 132/80 The patient was again putting on weight and the pigmentation was beginning to fade He was then allowed to get up, this was not accompanied by any ill effects while there was no obvious weakness With a further supply of doca sublingual tablets, a second course was begun on May 7 and for 3 weeks the patient was given twice the previous dose (5 mg q d s) There was no obvious change but at the end of the 3 weeks he had definitely relapsed a little—BP 100/76, with the pigmentation more definite and greater asthenia He became obviously more apathetic and drowsy An additional 5 mg of doca was then given by injection daily with rapid improvement The tablets were discontinued on June 6 and a further 5 mg injection substituted On this dosage (10 mg daily), as had been proved before, the patient remained very well, BP 120/85 *When discharged on June 17 he had put* on weight and the pigmentation was a good deal paler He was able to live a quiet life without any obvious tiredness At no *time during the treatment was there any* œdema Incidently, the pathology of the constitution was almost certainly tuberculous as an X ray of the chest revealed some soft infiltration of both lungs, with a slight opacity above the right renal shadow

From these two courses of sublingual doca it seems that at least 20–30 mg daily would have been necessary for maintenance, compared with the simpler 10 mg injection

My thanks are due to Dr H S Morley for permission to publish the case and to Messrs Organon Laboratories for providing the doca in sublingual tablets

M P HUTCHINSON

Royal West Sussex Hospital, Chichester

DIGESTIBILITY OF WHEATMEAL

SIR,—Dr Wright does not seem to have taken much notice of the devastating criticism which his first article has aroused (Bacharach, A L *Chem and Ind* 1941, 60, 791 Fraenkel, G *Ibid*, 1942, 61, 84 Lester Smith E *Ibid*, 1941, 60, 695), and still maintains that a switch over from 75% to 85% extraction seriously upsets the balance sheet of the national diet It is of course true, as has been officially stated, that higher extraction results in a loss of wheatfeed and consequently a reduction in milk production But it *also saves* annually *some 700,000 tons of wheat imports* if the same quantity of flour is milled in both cases In more normal times this shipping space can still be used for importing feeding stuffs and the cattle then receive just as much under a brown as under a white bread policy It is, therefore, not the brown bread policy as such which deprives the cattle of their food but the necessity of saving shipping space If this shipping space must be saved and white bread is to continue, there must be a reduction of about 12% in the bread eaten It seems hardly likely that Dr Wright or anybody else would recommend this latter procedure which would represent a much more serious loss of calories and of protein than that which adoption of wheatmeal bread is causing Therefore, with the present shipping position, the wheatmeal bread policy is in every important respect—protein, calories and vitamins—a far superior solution If there were no shipping difficulties we would have the dietary advantages of wheatmeal bread without losing a pint of milk Even if Dr Wright's claims on digestibility of National Wheatmeal were right, which seems doubtful, the loss of protein under such a scheme would be almost negligible (4000 tons p a), as I pointed out elsewhere, and there would be no loss of calories

Imperial College of Science and Technology G FRAENKEL

AIR ENTRY THROUGH TRANSFUSION SETS

SIR,—In his article of Aug 8 Mr Devas throws an interesting light on the possible results of air leaks but he makes no mention of their commonest cause It often happens that a patient having a transfusion of saline or blood suddenly requires the immediate intravenous administration of some drug such as '*Coramine*' The quickest and most convenient method of doing this is, of course, to inject the drug into the tubing of the transfusion set with a hypodermic syringe Unfortunately, this is only too often the cause of a permanent air leak This sabotage of the transfusion set is permissible where the patient's condition calls for instant interference but even in these cases the less damage done to the set the better I suggest that it should be a firm rule in every hospital where the standard sets are in use that this "needling" of the tubing should only be allowed in the six-inch length immediately proximal to the cannula This length is usually joined to the rest of the tubing by a glass connexion If replacement becomes necessary, it can then be made with far greater economy of rubber than if the damage is in other parts of the set, and, at the same time, location of air leaks is simplified

St Bartholomew's Hospital, E C 1 ROBERT J EVANS

TREATMENT OF RECENT WAR WOUNDS

SIR,—In a letter in the *Lancet* of July 4 I expressed my opinion that the training of Army surgeons in wound treatment had been and was still inadequate It was not, of course, my intention to imply that there was no training of this type I have since been told on very high authority that everything possible is being done in the way of training Army surgeons in wound treatment both in theory and its practical applications at home and abroad

Oxford J C SCOTT

CHALK IN BREAD

SIR,—In his letter of Aug 1 (p 139) Lord Horder says he supported the calcium-in-bread scheme because of the deficiency of calcium in our war-time diet In a review of the subject at the Royal Society of Medicine (*Brit med J* June 13, 1942, p 731) McCance said "Certain studies of the calcium intake in representative groups of people, adults and children, showed it to be much about the same as before the war" Widdowson and Alington, in their survey of middle-class diets (*Lancet*, 1941, ii, 361), found that the average daily intake of calcium increased from 0 63 g in 1935 to 0 77 g in 1941 In a Parliamentary reply (*Ibid*, July 25, 1942, p 110) we have lately been told that the total sales of milk for liquid consumption in the United Kingdom in 1939, 1940 and 1941 were 863 million, 937 million and 1065 million gallons Finally, we need only look at the cheese ration even before the present increase to know that Lord Horder's statement is unfounded

Liverpool I HARRIS

VESTED INTERESTS

SIR,—In connexion with a state medical service it is being stated that the "goodwill" of a medical practice is a vested interest, and by some that this is in the sickness of patients The latter is obviously ridiculous The professional ability and the personality of the doctor mainly constitute the goodwill of the practice These he cannot transfer to any purchaser, they are thus not saleable What money may have been spent on his education by his parents does not constitute any part of goodwill or vested interest, consequently this has no price The only vested interests so far as private practice (without NHI) is involved are the money spent on the doctor's house, instruments, &c These all have a price Doctors among themselves have instituted a pernicious custom of buying and selling practices and thus supporting medical agencies, but that is purely a matter for themselves and not one they have any right to ask the public to pay for When we come to the National Health Insurance practices there is a different factor The Government have definitely in their regulations recognised the transfer and sale of "panel" practices, and where doctors have had to pay for such portions of their practice they have a right to compensation if they do not continue in such practice because of Government action

W A G

PRACTITIONER AND PATHOLOGIST

SIR,—The application of laboratory methods to clinical medicine—in other words the practice of clinical pathology—demands, as you point out in your leading article of Aug 15, the combination of a sound knowledge of laboratory technique and clinical medicine From this it follows that clinical pathology can only properly be practised by those in close and continuing touch with clinical medicine, in laboratories forming an integral part of active hospitals Divorce of this work from hospitals and its centralisation in laboratories, whether publicly or privately owned, must inevitably result in the perpetuation of just those errors and abuses which you deplore It is disappointing to gain the impression that you are unaware of the great development of clinical pathology in many provincial hospitals in the past twenty years Actually there are now few parts of England where the services of a properly staffed department of clinical pathology are not made available through the principal hospitals of the area In most of these the facilities which you demand for consultation between practitioner and clinical pathologist are provided That the same cannot be said of Scotland is due to that centralisation of this class of work which you seem to approve

Clinical pathological services would be even more generally available throughout England if medical students in the past had been encouraged to interest themselves in this special branch of medicine Sojourn in the pathological laboratories of a hospital, no matter how well equipped, will not by itself make a clinical pathologist Clinical pathology is something more than "hospital pathology" it demands a training which will make the clinical pathologist as much at home at the bedside as at the laboratory bench

Wolverhampton S C DYKE

BABEL IN ENDOCRINOLOGY

SIR,—There has recently been introduced into clinical medicine a substance which has a progestational action when taken by mouth It is chemically known as anhydrohydroxyprogesterone, pregneninolone, or ethinyltestosterone It is sold by various manufacturers as 'Lutocyclin Oral,' 'Progestoral,' 'Lutogyl,' 'Proluton C,' and, for all I know, under another half-dozen names Now the GMC has decided that it should be called ethisterone, thus making confusion worse confounded There was no need of a new name, still less of a name which draws attention to the chemical relationship of the substance to testosterone (which is of no practical importance) instead of to progesterone (which is) Why should not the "approved name" be anhydrohydroxyprogesterone ?

If these new and often very useful remedies are to come into general use, something must be done about nomenclature Œstradiol benzoate has at least a dozen trade names Insulin has only one The first reliable manufacturer to market his products as œstrone (Smith), progesterone (Smith) and so on through the whole range of hormones will receive the unswerving support of this clinic, and, I think, of the whole profession Meanwhile, would the GMC think again, please ?

Endocrine Clinic Westminster Hospital RAYMOND GREENE

IN Dr Paramore's letter of Aug 8 (p 171) read "When renal failure has developed, the best posture is the semi prone with the feet somewhat raised "

Obituary

RONALD STEWART

M B EDIN ; SURGEON LIEUTENANT R N V R

THE parents of Surgeon Lieutenant Ronald Stewart, who lost his life on active service last December, have been informed that their son has been mentioned in despatches for his devotion to duty as one of a rescue party sent to the help of a bombed ship, when he worked for many hours to relieve the sufferings of the survivors and did much to aid their recovery Stewart was educated at Edinburgh Academy and Edinburgh University where he graduated in 1940 when he was still only 21 After a few locums he was appointed house-surgeon at Leith Hospital, but he had already volunteered for the RNVR and in April, 1941, received his commission, in due course he was appointed to HMS *Audacity* Ronald Stewart was a farmer's son He loved the countryside, its people and its sports He could cast a pretty fly and was something of an expert on the bird-life of Midlothian, having made several expeditions to the Isle of May to study the migrations His happy personality charmed all who met him, and his sincerity, kindness and wit won him many friends

WILLIAM ELLIOT YOUNG

B M OXFD ; CAPTAIN R A M C

Captain W E Young, only son of Sir Alban Young, was killed in action in Libya in May William Elliot Young, who was born in 1910, was educated at Marlborough and Balliol College, Oxford He went on to Guy's for his clinical years and qualified LMSSA in 1937, taking his degree the following year While a resident at Guy's he met Miss Mary Macdonald, daughter of the Rev J Macdonald, who was a nurse at the hospital. They were married at the outbreak of war and Dr Young immediately volunteered for the RAMC He was called up a few months later and in January, 1940, sailed for India He accompanied the Indian division to Eritrea the same year and at the end of that campaign was sent to Libya His widow is still in India with their one son

---

Lieut -Colonel AILWYN HERBERT CLARKE, RAMC, died on June 23 in a prisoner-of-war camp in Italy at the age of 59 At the beginning of the last war he served in France as a Red Cross dresser but eventually returned to finish his medical studies at St Thomas's As soon as he qualified MRCS in 1916 he took a commission in the RAMC and went back to France in October He was awarded the MC for conspicuous gallantry and devotion to duty on Oct 10, 1918, when under heavy shelling he proceeded several times to the sunken road south-east of Rambourlieux Farm near Le Cateau to attend to wounded. He did not desist until he had succeeded in dressing all his patients and in getting them carried safely away During the present war Clarke served in the Middle East from June, 1940, till he was captured in April of the next year He held the temporary rank of lieut -colonel

DR. DAWTREY DREWITT —Sir Walter Langdon-Brown writes . Sir William Hale-White's beautiful little tribute reminds one of another trait in Dr Drewitt's delightful character—the blend of old-fashioned courtesy with a youthful eagerness to know of any new thing Some of us used to tell him that as he was born in leap year on Feb 29 he only aged one year in every four At 92 he was still a welcome and interested participant at his dining clubs With his many interests it must have grieved him to say, as he did in his last letter to me on May 16, " I know nothing of the world beyond my bedroom "

Public Health

Iceland

FROM an English summary of the 1939 public health report of Iceland we learn that the population of that island was 120,264 , its birth-rate 19 4 , death rate 9 7, a low record , infantile mortality 37 3 (in 1938 it was 28 3, a low record) , maternal mortality 2·1 , and that 87 8% of the babies are fully breast-fed The disease statistics given for the ten years 1930-39 include many conditions for which morbidity returns are rarely available Thus, in the ten years there were 51,764 notifications of tonsillitis, but only 4 deaths are attributed to this cause ; the attack-rate works out at about 1 person in 20 per annum, or one attack per 20 years of life Of respiratory catarrh there were 115,731 notifications with 22 deaths , this works out at one attack per 10 persons per annum Of influenza 55,165 notifications are recorded but only 190 deaths The annual variation of numbers in tonsillitis was between 3909 and 6713 ; in respiratory catarrh between 8549 and 16,938 , in influenza between 212 and 21,977 How far the figures are reliable one cannot say The disease which shows the greatest epidemic periodicity is whooping-cough, of which 8267 cases were notified in 1935 and only 375 in the other nine years In Britain and the United States whooping-cough shows the least periodic variation of the endemic infections Hydatid disease occurs in Iceland (102 cases with 54 deaths in 10 years) There were 35 known cases of leprosy in 1930, but the number had fallen to 21 by 1939 Gonorrhœa gives about 500 new cases a year ; syphilis an average of 24 only Chicken pox and herpes zoster are both notifiable in Iceland In view of the undoubted relationship of these two virus diseases, it is interesting that their incidences show no tangible correspondence In the death table, old age stands first with 15% of all deaths, cancer second with 14%, then pneumonia, heart disease and apoplexy with rather more than 10% each, and then tuberculosis with 8%

Infectious Disease in England and Wales

WEEK ENDED AUG 8

Notifications —The following cases of infectious disease were notified during the week smallpox, 0 , scarlet fever, 1340 , whooping-cough, 953 , diphtheria, 580 , paratyphoid, 15 , typhoid, 6 , measles (excluding rubella), 5669 , pneumonia (primary or influenzal), 413 , puerperal pyrexia, 142 , cerebrospinal fever, 77 , poliomyelitis, 10 ; polio-encephalitis, 4 ; encephalitis lethargica, 4 ; dysentery, 82 ; ophthalmia neonatorum, 81. No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospital of the London County Council on Aug 5 was 1542, including scarlet fever, 265 ; diphtheria 155 , measles 384 , whooping cough 233 , enteritis 65 chicken pox, 108 , erysipelas, 40 , mumps, 60 , poliomyelitis, 1 , dysentery, 23 , cerebrospinal fever, 8 ; puerperal sepsis, 16 , enteric fevers, 4 , german measles, 4 , other diseases (non-infectious), 95 , not yet diagnosed, 101

Deaths —In 126 great towns there were no deaths from scarlet fever, 1 from an enteric fever, 8 (0) from measles, 2 (1) from whooping-cough, 11 (1) from diphtheria, 34 (3) from diarrhœa and enteritis under two years, and 10 (0) from influenza The figures in parentheses are those for London itself

Stockport reported the fatal case of enteric fever Birmingham had 4 deaths from diarrhœa, and Liverpool 3 from measles

The number of stillbirths notified during the week was 206 (corresponding to a rate of 35 per thousand total births), including 14 in London

---

THE Ministry of Health memo on scabies and how to deal with it has been revised and extended (H M Stationery Office, pp 4, 1*d*) It now includes a description of the life history and habits of the acarus, a clear account of the symptoms and differential diagnosis (by Dr A M H Gray) and fuller advice on treatment Benzyl benzoate is still favoured, but where the patient must do his own application the memo advises sulphur ointment in two-thirds BP strength

Notes and News

ANCHORING HOSPITAL PERSONNEL

THERE is reason to think that if B1 medical officers hospitals are allowed to transfer freely from one ospital to another some hospitals will go short of staff posts, it will be recalled[1] are whole-time posts, not lways resident, for which previous experience is essential, ey are subdivided into B1 and B2 posts B1 posts clude the RSO RMO, registrar and others of equivalent nk at voluntary hospitals, and appointments with a enure of more than one year and carrying a salary of ore than £350 at a municipal hospital, all the remaing B posts are B2 Hitherto B1 posts have been filled rom among those holding B2 posts, but now that men t for military service holding B2 posts are to be recruited or service with the Forces at the end of their six months f office (Ministry of Health circular 2660), vacant B1 posts ill have to be filled by women, men who are physically nfit for the Services or foreign doctors; the supply is hus limited At the suggestion of the Central Medical Var Committee the Minister of Health has agreed that he movement of holders of B1 posts should be controlled, nd has decided to use his powers under Defence Regulaion 58A. Thus if the holder of a B1 post wants to leave is hospital (except to transfer to another hospital nder the same authority) and his hospital thinks it ssential to retain him, the senior regional officer must e informed of all the circumstances or, in the case of he London sector hospitals, the information must be ent to the headquarters of the ministry The doctor's position will then be investigated, in consultation with representatives of the CMWC, from the points of view of the two hospitals affected; and unless the proposed transfer is one which the minister thinks should be reasonably allowed the doctor will be directed to stay where he is The minister feels confident that, knowing the difficulties in which hospitals are placed by the withdrawal of personnel for the Forces, doctors will make the best of this temporary restriction of movement The arrangements will come into force in November.

PSYCHOTHERAPY IN GERMANY

SOME therapeutic trends in Central-European medicine are reflected in a postgraduate lecture by J E Staehelin.[2] He is less enthusiastic than most English and American psychiatrists about convulsion therapy in depressions and involutional melancholia, and advises caution because of the dangers of fractures and circulatory and cerebral damage He is definitely opposed to the use of convulsion therapy in the outpatient department or consulting-room, and he has seen plenty of relapses after temporarily successful treatment He advocates insulin treatment without the production of deep coma, continued over a long period, and also favours intensive treatment with sex hormones and several other methods such as treatment with acetylcholine, or tincture of opium Amphetamine and related "waking-up" compounds are recommended for simple retarded depressions with apathy as the main symptom and prevailing vagotonia, but are contra-indicated, he considers, in all agitated and restless cases Treatment with amphetamine should be interrupted for a few days after a week or two, to avoid the danger of addiction and the insomnia which this drug produces when taken in excess. In discussing epilepsy he enumerates the factors which favour the onset of convulsions, among which is reduced oxygenation of the brain which may result during sleep, especially when the pillows are too soft and the room ill-ventilated, or when the patient has cardiac or pulmonary disease Shifting of the acid-base equilibrium towards alkalosis may also favour the onset of fits, and to promote acidosis he advises periodic fasting, pyrotherapy and a ketogenic diet; since hyperventilation favours alkalosis he discourages patients from taking excessive physical exercise A high blood-chloride is also to be avoided, and he recommends that a diet poor in salt should be tried first in all mild cases A low blood-sugar, especially in the morning, may provoke convulsions, and he believes in careful regulation of the carbohydrate intake so as to avoid this Water retention, associated with a high chloride content of the body and excess of posterior pituitary hormone, should be counteracted by a diet poor in fluids and by boric acid preparations which help to dehydrate the brain and favour acidosis He advises the relief of increased intracranial pressure—for example, in status epilepticus—by lumbar puncture For the hyperexcitability of the central nervous system he suggests the usual sedative drugs: bromides, and phenobarbitone and other barbiturates Disturbances of the vegetative nervous system are improved, he finds, by atropine Failing circulation and a tendency to vascular spasms he treats with cardiac stimulants such as caffeine and nikethamide, and he advises thyroidectomy in suitable cases

THE ILLICIT USE OF NARCOTIC DRUGS

THE justice of the warning, issued by the Advisory Committee of the League of Nations on Dangerous Drugs, against any relaxations during war conditions is borne out by the statistics of seizures of illicit traffic in 1939 Thus in Burma in that year 5644 kg of opium (raw and prepared) were seized, in Turkey 2291 kg of raw opium, in Egypt 1110 kg of opium, 24 kg. of heroin and 723 kg of hashish In the United States, where the manufacture of heroin is forbidden 86 kg was confiscated, and no less than 22,623 kg of Indian hemp including marihuana (the dried flowering tops of the cannabis plant) were seized in 1939 Japan has never been very zealous in carrying out the various opium conventions to which she is a party and in the parts of China which she has over-run there seems to have been encouragement rather than repression of the abuse of habit-forming narcotics The advance made in the Far East, under international conventions since 1912, in restricting to medical and legitimate purposes opium, prepared opium, morphine, heroin and cocaine and their preparations appears to have been checked and reversed with the physical and moral results attending such reaction

PULMONARY EMBOLISM AFTER VARICOSE-VEIN INJECTION

A FATAL case of pulmonary embolism has prompted A M Vaughn and W. M Leis (*J Amer med Ass* 1942, 118, 1293) to draw attention to the danger of injecting varicose veins in patients who are not ambulatory during treatment They also emphasise the known fact that thrombophlebitis increases the chance of embolus formation. Their patient was a woman of 65, active and well except for ulceration of a patch of skin on the anterior surface of the left leg at the junction of its middle and lower thirds In the patellar and popliteal regions there was reddish-blue discoloration of the skin, which was, however, unbroken. The veins of the leg were enlarged and tortuous There seems to have been no suspicion of phlebitis On March 28, 2 c cm of 5% sodium morrhuate was injected into a varicose vein just proximal to the ulcer Evidently there was no improvement from this one injection, and the patient was admitted to hospital on April 14 From this time until her death on April 28 she was kept in bed. Hot fomentations and a heat cradle were applied to the leg, and four injections of 1 5 c cm of 5% sodium morrhuate were given between April 16 and 20 After the last injection the ulcer was healing rapidly The woman died suddenly on April 28, and autopsy showed that both main pulmonary arteries and their first division were occluded by coiled emboli The left common iliac vein was distended with blood; its tributaries deeper in the leg were occluded by antemortem clots There was generalised arteriosclerosis especially of the abdominal aorta and the coronary arteries Vaughn and Leis believe that the enforced rest and immobility of the patient were the main factors in promoting the thrombophlebitis, and that it is wrong to stop the daily routine activities of a patient during injection treatment of varicose veins Their view is supported by an analysis of 44 published cases of fatal pulmonary embolism following this treatment Incidentally, the analysis shows that no one solution is particularly blameworthy Fatalities have occurred after injection of a great variety of substances, including sodium morrhuate, quinine and urethane, sodium chloride, dextrose and invertose

Medical Honours

The following awards have recently been made

GM—The late Surgeon Lieut Commander R M Bremner, MB EDIN, RN

MC—Captain R E S Lewis, MB EDIN, RAMC, Captain C D Weir, MB EDIN, RAMC Captain A G J P Fernandes, MB, IMS, and Lieutenant D J Burnett, IMS

RNVR Officers Decoration—Surgeon Commander W H Butcher, DM OXFD Surgeon Commander J B Oldham, FRCS, and Surgeon Commander H M Petty, MB LEEDS

Foreign Awards—Norwegian Military Cross with Sword—Lieut-Colonel (A/Colonel) A J Beveridge MC, MB NUI, RAMC, and Captain W M Burgess, MB, RAMC *Greek War Cross (third class)* Surgeon Lieut Commander J C Moor, MB DURH, RNVR

Medical Casualties

The following casualties have been announced

Died—Lieut Colonel Homi Rustomji Cursetji, MB BOMBAY, DOMS, IMS

Missing—T/Surgeon Lieutenant A P Curtin, MRCS, RNVR

Previously missing, now officially reported P of W—Major I A B Cathie, MD LOND, RAMC

P of W—Captain E F M Caraher, MB NUI, RAMC, Captain A F Murray, MB ABERD, RAMC, Major J M Officer, MB EDIN, RAMC Lieutenant A C Price, MRCS, RAMC, Major L F Richmond MB DURH RAMC, WS/Captain R L Sanderson, MB EDIN, RAMC, and WS/Captain D B Watson, MB RAMC

Wounded—A/Colonel D V O'Malley, OBE, MB NUI, IMS

Irish Dietetic Council

The first annual report of the Dietetic Council, appointed last autumn by the Medical Association of Eire, is a record of useful work under the chairmanship of Dr P T O'Farrell, with Prof W J E Jessop as hon secretary The council has induced the St John Ambulance Brigade, the Irish Red Cross Society, the Order of Malta Ambulance Corps, and the School of Domestic Science to hold classes in dietetics Several papers on dietetic subjects have been published in the *Journal of the Irish Medical Association*, and the council has been in constant touch with Government departments on questions of food supplies and of health

India's War-time Medical Services

Unlike other arms of the defence services, field units of the Indian medical services do not exist in peace time, but since the beginning of the war over 300 have been raised and are now serving in the United Kingdom, Middle East, East and West Africa, Palestine, Iraq, Iran, Ceylon, the Seychelles and in India itself Ambulance trains have also been provided for railways in the Eastern theatres of war and hospital ships were used for the evacuation of casualties from Iraq, Iran, Burma, Assam and Eastern Bengal To meet these demands many new training schools have been started and the old ones rapidly expanded A centrally controlled Army medical store organisation has also been created which, in addition to the normal calls on its resources, has helped the American, Chinese and Russian armies

Training School for Mental Nurses

London needs 700 mental nurses and to encourage the flow of recruits the LCC have set up a training school at Claybury Hospital which will give new entrants a gradual introduction to their work The school is intended to act as a feeder to the council's mental hospitals to the north of the Thames—Claybury, Friern, Leavesden and St Bernard's—and if it is a success the council will consider setting up schools at other hospitals The school accommodates twenty nurses at a time Each has her own bedroom, is provided with uniform and receives the pay of a probationer The four-week course includes a good deal of individual tuition, lectures and demonstrations in elementary nursing, and visits to wards, kitchens, laundries and laboratories

PREMAXILLARY CYSTS—Dr H T Roper Hall, of 43a, Calthorpe Road, Five Ways, Birmingham, 15, asks for details, models, radiograms, specimens or histories of cysts in the premaxillary region, especially those in the region of the lateral tooth, in which diagnosis was complicated or origin uncertain, and the teeth not apparently involved

Major JOHN GILMOUR, FRCSE, RAMC retd, an officer of the Department of Health for Scotland, has been appointed a temporary inspector under the Cruelty to Animals Act 1876

A PRIVATE investigation quoted by Dr Gustaf Alegård in *Fackföreningsrörelsen* showed that in Stockholm the infant mortality per 1000 live births was 14 3 where the father's income was over 10,000 kronor (£600) a year, and 48 9 where his income was less than that The rate for the whole country for 1940 was 38 6, in a prosperous farming district in southern Sweden it was 32 and it rose to 67 in the sparsely settled extreme north

Births, Marriages and Deaths

BIRTHS

ANDERSON—On Aug 6, in London, the wife of Major Ian McAllister Anderson RAMC—a daughter

BARRY—On Aug 8, at Dublin, the wife of Surgeon Commander T L Barry, RN—a son

BROMLEY—On Aug 12, at Bury St Edmunds, the wife of Dr J W Bromley—a son

CRESSALL—On Aug 11, at Oxford, the wife of Captain S F V Cressall, RAMC—a son

EXNER—On Aug 11, at Winchester, the wife of Dr G G Exner of Harley Street, W 1—a daughter

HANCOCK—On Aug 12, at Aylesbury, the wife of Dr F R Thompson Hancock, of Stoke Mandeville—a son

HENSON—On Aug 13, at Bath, the wife of Captain Ronald A Henson, RAMC—a daughter

KENNERLEY—On Aug 10, at Harborne, the wife of T/Major T A S Kennerley, RAMC—a son

LEWIS—On Aug 11, at Woking, the wife of Surgeon Lieut Commander B S Lewis, RN—a son

RIGBY JONES—On July 31, in London, Dr Peggy Rigby Jones (née Permain), the wife of Lieutenant Guy Rigby Jones, RAMC—a son

ROBERTSON—On Aug 12, at Evesham, the wife of Dr J M Robertson—a son

MARRIAGES

ADLINGTON—LAYLAND—On Aug 10 at Torquay, John Adlington, MB, surgeon lieutenant RNVR, to Nora Frances Layland WRNS

PIGGOTT—POWLESLAND—On Aug 8, at Newton Abbot F Stanley L Piggott MRCS, of Teignmouth, to Nancy Powlesland

SPENCE—PIKE—On Aug 10, at Oxford, James Henderson Spence, MB, to Edith Pike

DEATHS

ASHE—On Aug 7, at Ombersley Worcs, Henry Park Ashe MRC

HENDRY—On Aug 13, at Rugby, Robert Applegarth Hendry, MD LOND, MB LPOOL formerly of Liverpool

INSTONE—On Aug 14, Noel Instone, MB LOND, at Addison Road, W 14

WALKER—On July 24, William Walker, MC, MD ABERD major RAMC retd, pathologist to the Tynemouth Victoria Infirmary, aged 51

SIR HAROLD SCOTT will retire at the end of August from the post of director of the Bureau of Hygiene and Tropical Diseases which he has held since 1935 The Secretary of State for the Colonies has appointed Dr Charles Wilcocks, the present assistant director of the bureau, to be acting director

Mr BOWDLER HENRY, MRCS, LDS, has been appointed honorary consulting oral surgeon and consultant adviser to the Royal Netherland Army, the Fighting French Force, the medical section of the Czechoslovak Red Cross, the central committee of the Polish Red Cross, and the Royal Norwegian Ministry of Social Welfare

ALVARENGA PRIZE—The College of Physicians of Philadelphia have awarded this prize for 1942 to Dr Edwin J Cohn, professor of physiological chemistry at Harvard University, in recognition of his contribution to our knowledge of blood proteins

The AMERICAN RED CROSS HARVARD FIELD HOSPITAL UNIT which was established in England two years ago has now been taken over by the United States Army It is to be used as the central medical laboratory for the American forces in this country

Messrs MAY and BAKER have issued their 'Stovarsol Vaginal Compound' (S V C) tablets for the treatment of trichomonas infection in a new shape—rectangular with rounded corners—and with a new excipient It is claimed that these changes will ensure greater ease of insertion, more regular disintegration and less tendency to breakage, and will promote an acid reaction in the vagina

PETHIDINE HYDROCHLORIDE, a synthetic compound closely allied to morphine in composition, and combining the analgesic effect of morphine with the spasmolytic effect of the atropine group and papaverine, is issued by Roche Products in 50 mg ampoules for subcutaneous, intramuscular or intravenous injection, and in 25 mg tablets

ON page 190 of Aug 15 we said there is only one chair of pædiatrics in England, there are in fact two—at Birmingham (Prof L G Parsons) and at Leeds (Prof C W Vining)

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

1942 Students Guide 1943

THE LANCET

MEDICINE TOMORROW[1]

R. S. AITKEN
M.D. N.Z., D.PHIL. OXFD, F.R.C.P.
REGIUS PROFESSOR OF MEDICINE IN THE UNIVERSITY OF ABERDEEN

THE most striking change in the organisation of the medical profession within the community, during the last hundred years, has been the development of specialisation. Besides those who practise the major specialties, there are men who specialise in narrow groups of diseases like the venereal diseases, or in single diseases like pulmonary tuberculosis, and men and women who spend decades doing little beyond the routine examination of school-children. Physicians subdivide themselves into neurologists, cardiologists, chest physicians and so on, while there are specialist surgeons who narrow their field to one small region of the body, almost to one kind of operation. (There was even a group of surgeons in the Royal Society of Medicine who segregated themselves in a subsection of proctology, wilfully imprisoning their narrow lives within the muddy walls of the rectum.)

OVERGROWTH OF SPECIALISATION

It is worth inquiring what are the causes of this papilliferous growth of specialism. The first is obvious: knowledge and technique in medicine have advanced so far that one man cannot master and develop more than one small field in a lifetime. Differentiation of function leads to better performance, and to that end specialism is necessary and good. Another cause, however, is that in large towns specialism offers an easier life, more regular hours and higher fees than general practice; it has therefore attracted those who coveted the prospect of large rewards for smaller effort, and many who could afford to specialise had no greater intellectual ability than others who have had to devote themselves to general practice. A third cause is the development of specialist state services. The voluntary hospitals were unable to provide beds enough in suitable surroundings for the treatment of pulmonary tuberculosis; so the state set up sanatoria and dispensaries for the management of that disease, and a special service of tuberculosis officers who deal with that condition and that alone. The practitioners and the hospitals between them were incapable of detecting and treating venereal disease; so the state stepped in and created another self-contained isolated special service. The practitioners could not or would not keep a medical eye on school-children at frequent intervals (which is a good thing to do), for the simple reason that they were not paid for it; so a school medical service was instituted. For just the same reason now we see maternity and child-welfare clinics being created, and even special doctors undertaking the simple injections necessary for diphtheria immunisation. The motive behind all these state services is good—they are directly aimed at the welfare of the people. But notice that they all arose because of the failure of the voluntary hospital system and the general practitioner system to meet the needs of the people. They did not come into being because the work involved was so difficult as to require special ability or training; it was simply that doctors had to be paid salaries to work in these special fields because the independent practitioners were not doing the work.
